(57) **ABSTRACT**

A touch-sensing liquid crystal panel and a fabrication method thereof are provided. The touch-sensing liquid crystal panel includes a color filter substrate and a transistor substrate. In the fabrication method, at first, a first glass substrate is provided. Thereafter, a sensing matrix is formed on a first surface of the first glass substrate at a baking temperature. The sensing matrix is formed from indium tin oxide (ITO), and a sheet resistance of the sensing matrix is equal to or less than 30 ohm/square. Then, color filters and a common electrode are disposed on a second surface of the first glass substrate to form a color filter substrate, wherein the second surface is opposite to the first surface. Thereafter, the transistor substrate is provided and combined with the color filter substrate. Thereafter, a slimming process is performed to slim a second glass substrate of the transistor substrate.

TOUCH-SENSING LIQUID CRYSTAL PANEL AND FABRICATION METHOD THEREOF

RELATED APPLICATIONS

[0001] This application is a continuation application of U.S. application Ser. No. 14/187,312, filed on Feb. 23, 2014, which claims priority to Chinese Application Serial Number 201310251795.9, filed Jun. 24, 2013. The entire disclosures of all the above applications are hereby incorporated by reference herein.

BACKGROUND

[0002] 1. Field of Invention

[0003] The present invention relates to a touch-sensing liquid crystal panel and a fabrication method thereof. More particularly, the present invention relates to a touch-sensing liquid crystal panel having a touch-sensing matrix using On Cell technology and a fabrication method thereof.

[0004] 2. Description of Related Art

[0005] In recent years, thin and light flat panel displays become popular displays used in various electronics. In order to enable information products to achieve the objects of convenient usage, concise appearance, and multiple functions, many information products use touch panels as input devices instead of traditional keyboards, mice, etc.

[0006] With rapid development flat display and touch panel technologies, some electronic products combine the touch panel with a display panel to form a touch-sensing display panel, so as to provide users with a greater viewable screen area and more convenient operation modes under the condition of limited volumes. Because the touch-sensing display panel has the display function of the display panel and convenience of input operation of the touch panel, the touch-sensing display panel has gradually become an important component applied in many electronic products such as a handheld PC, a personal digital assistance (PDA), or a smart phone.

[0007] The operation principle of the touch panel is based on that, when a conductor object (such as a finger) touches a touch-sensing matrix of the touch panel, a electrical property (such as electrical resistance or capacitance) of the touchsensing matrix is changed accordingly to result in a change of a bias voltage applied on the touch-sensing matrix. The change of the electrical properties is converted to a control signal outputted to an external control circuit board, and then a processor performs data calculation in accordance with the control signal to obtain a result. Thereafter, the external control circuit board outputs a display signal to the display panel, and an image is presented to users through the display panel.

[0008] In the current various technologies of touch panels, On Cell technology is one of the most popular technologies, because the On Cell technology has advantages of low cost and convenience for assembling. In the On Cell technology, a sheet resistance of the touch-sensing matrix affects the performance of touch-sensing operation. For example, if a touchsensing matrix has a greater sheet resistance, a touch-sensing driver circuit of the touch-sensing matrix needs more power to perform the touch-sensing operation.

[0009] Therefore, there is a need to provide touch-sensing liquid crystal panel and a fabrication method thereof having a sensing matrix with a lower electrical resistance.

SUMMARY

[0010] Therefore, an aspect of the present invention provides a touch-sensing liquid crystal panel and a fabrication method thereof. The fabrication method uses high temperature baking technology to form a sensing matrix with lower electrical resistance to provide the touch-sensing liquid crystal panel having better touch-sensing performance.

[0011] According to an embodiment of the present invention, the touch-sensing liquid crystal panel includes a color filter substrate, a transistor substrate and a liquid crystal layer. The color filter substrate includes a first glass substrate, a sensing matrix, color filters and a common electrode layer. The first glass substrate has a first surface and a second surface, wherein the first surface is opposite to the second surface. The sensing matrix is disposed on the first surface of the first glass substrate, wherein the sensing matrix is formed from indium tin oxide (ITO), and the sensing matrix has a sheet resistance smaller than or equal to 30 ohm/square. The color filters are disposed on the second surface of the first glass substrate. The common electrode layer is disposed on the color filters. The transistor substrate includes a second glass substrate and a pixel layer. The second glass substrate is treated by a slimming process and has a thickness smaller than 0.2 mm. The pixel layer is disposed on the second glass substrate, wherein the pixel layer includes pixel units, and each of the pixel units includes a switching transistor and a pixel electrode. The liquid crystal layer is disposed between the color filter substrate and the transistor substrate.

[0012] According to another embodiment of the present invention, in the fabrication method of the e touch-sensing liquid crystal panel, at first, a color filter substrate is fabricated. In the operation for fabricating the color filter substrate, at first, a first glass substrate is provided, wherein the first glass substrate has a first surface and a second surface, and the first surface is opposite to the second surface. Thereafter, a sensing-matrix-forming step is performed to form a sensing matrix on the first surface of the first glass substrate at a predetermined process temperature, wherein the sensing layer is formed from indium tin oxide and a sheet resistance of the sensing layer is smaller than or equal to 30 ohm/square. Then, filters are formed on the second surface of the first glass substrate. Thereafter, a common electrode layer is formed on the color filters to form the color filter substrate. After the step for fabricating the color filter substrate, a transistor substrate is provided. The transistor substrate includes a second glass substrate and a pixel layer. The pixel layer is formed on the second glass substrate, wherein the pixel layer includes pixel units, and each of the pixel units includes a switching transistor and a pixel electrode. Then, the color filter substrate is combined with the transistor substrate and a liquid crystal layer is formed between the color filter substrate and the transistor substrate to form a liquid crystal panel. Thereafter, a slimming process is performed on the liquid crystal panel to slim the second glass substrate of the liquid crystal panel.

[0013] It can be understood from the above descriptions that the fabrication method of the touch-sensing liquid crystal panel forms a sensing matrix with a sheet resistance equal to or smaller than 30 ohm/square, so as to provide the touch-sensing liquid crystal panel having better performance on touch-sensing. In addition, one side of the touch-sensing liquid crystal panel is slimed to enable the touch-sensing liquid crystal panel to be thinner and lighter.

BRIEF DESCRIPTION OF THE DRAWINGS

[0014] In order to make the foregoing as well as other aspects, features, advantages, and embodiments of the present invention more apparent, the accompanying drawings are described as follows:

[0015] FIG. **1** is a flow chart showing a fabrication method of a touch-sensing liquid crystal panel in accordance with an embodiment of the present invention;

[0016] FIGS. 2*a*-2*f* are cross-sectional views of the touchsensing liquid crystal panel corresponding to the steps of the fabrication method in accordance with an embodiment of the present invention;

[0017] FIG. **3** is a flow chart showing a fabrication method of a touch-sensing liquid crystal panel in accordance with another embodiment of the present invention;

[0018] FIGS. 4*a* and 4*b* are cross-sectional views of the touch-sensing liquid crystal panel corresponding to the encapsulating steps of the fabrication method in accordance with an embodiment of the present invention; and

[0019] FIG. **5** is a structure diagram showing a pattern of the sensing matrix in accordance with an embodiment of the present invention.

DETAILED DESCRIPTION

[0020] Reference will now be made in detail to the present preferred embodiments of the invention, examples of which are illustrated in the accompanying drawings. Wherever possible, the same reference amounts are used in the drawings and the description to refer to the same or like parts.

[0021] Referring to FIG. 1 and FIGS. 2*a*-2*f*, FIG. 1 is a flow chart showing a fabrication method 100 of a touch-sensing liquid crystal panel in accordance with an embodiment of the present invention, and FIGS. 2*a*-2*f* are cross-sectional views of the touch-sensing liquid crystal panel corresponding to the steps of the fabrication method 100. In the fabrication method 100, at first, a step 110 is performed for providing a color filter substrate. In this embodiment, the step 110 for providing the color filter substrate includes step 112 for providing a substrate, step 114 for forming a sensing matrix, step 116 for forming color filters and step 118 for forming a common electrode. In the following descriptions, the step 110 for providing the color filter substrate is described in detail.

[0022] In the step 110 for providing the color filter substrate, at first, the step 112 is performed to provide a glass substrate 210, as shown in FIG. 2*a*. The glass substrate 210 has a first surface 212 and a second surface 214, wherein the first surface 212 is opposite to the second surface 214.

[0023] Then, the step 114 for forming a sensing matrix is performed to form a sensing matrix 220 on the first surface 212 of the glass substrate 210 at a predetermined baking temperature, as shown in FIG. 2b. In this embodiment, the predetermined baking temperature is greater than 230° C., and a sputter technology is used to form the sensing matrix 220 on the glass substrate 210. However, embodiments of the present invention are not limited thereto. In addition, the sensing layer 220 is formed from indium tin oxide (ITO) and the sensing layer 220 has a thickness ranging from 600 Angstrom to 1400 Angstrom. The step 114 is performed for forming the sensing matrix 220 having a sheet resistance smaller than or equal to 30 ohm/square, thereby decreasing the power needed by a touch-sensing circuit for touch-sensing operation. In this embodiment, the pattern of the sensing matrix 220 id formed by using a photolithography process, and the sensing matrix **220** has perpendicular ITO lines L, as shown in FIG. **5**. However, the shape of the pattern of the sensing matrix **220** is not limited thereto.

[0024] It is noted that the touch-sensing panel of this embodiment is fabricated by using On Cell technology, and thus only one mask is needed in the step **114** for forming the pattern of the sensing matrix **220**.

[0025] After, the step 114 for forming the sensing matrix, the steps 116 and 118 are sequentially performed to form color filters 230 and a common electrode COM on the second surface 214 to obtain a color filter substrate P, as shown in FIG. 2c. The color filters 230 include color resistors 232 and black matrixes 234. In this embodiment, the color resistors 232 include red resistors, blue resistors and green resistors, but embodiments of the present invention are not limited thereto. The common electrode COM is formed on the color filters 230, and thus the color filters 230 are disposed between the glass substrate 210 and the common electrode COM.

[0026] After the step 110 for providing the color filter substrate, a step 120 is performed for providing a transistor substrate 240, as shown in FIG. 2*d*. The transistor substrate 240 includes a glass substrate 242 and a pixel layer 244. The pixel layer 244 is formed on the glass substrate 242 and includes pixel units (not illustrated). Each of the pixel units includes switching transistors and a pixel electrode to sequentially receive image data signals to control alignment of liquid crystal molecules in a liquid crystal layer.

[0027] After the step 120 for providing the transistor substrate 240, a step 130 is performed to combine the transistor substrate 240 with the color filter substrate P and to dispose the liquid crystal layer LC between the transistor substrate 240 and the color filter substrate P to obtain a touch-sensing liquid crystal panel 200, as shown in FIG. 2*e*, wherein the common electrode COM of the touch-sensing liquid crystal panel 200 is located between the liquid crystal layer LC and the color filters 230. In this embodiment, the combination of the transistor substrate 240 and the color filter substrate P are performed by using a sealant, but embodiments of the present invention are not limited thereto.

[0028] After the step **130** for combining the transistor substrate **240** with the color filter substrate P, a slimming step **140** is performed to slim the touch-sensing liquid crystal panel **200**, as shown in FIG. *2f*. In this embodiment, the slimming step **140** is performed on the glass substrate **242** of the transistor substrate **240** to reduce the thickness of the glass substrate **242** from 0.4 mm to 0.2 mm. In other words, the thickness of the glass substrate **242** is reduced 50%.

[0029] It can be understood from the above descriptions that the fabrication method **100** of the touch-sensing liquid crystal panel uses the step **114** to provide the sensing matrix **220** having a sheet resistance smaller than or equal to 30 ohm/square to decrease the power needed by a touch-sensing circuit for touch-sensing operation. In addition, the fabrication method **100** of the touch-sensing liquid crystal panel includes a slimming process to provide the thin and light touch-sensing liquid crystal panel **200**.

[0030] Referring to FIG. 3, FIG. 3 is a flow chart showing a fabrication method 300 of a touch-sensing liquid crystal panel in accordance with another embodiment of the present invention. The fabrication method 300 is similar to the fabrication method 100, but the difference is in that the fabrication method 300 further includes encapsulating steps 312 and 320. [0031] The encapsulating step 312 in a step 310 for providing a color filter substrate is performed between the steps 114

and **116**. The encapsulating step **312** is performed before the step **116** to form an encapsulation layer **410** on the sensing matrix **220**, as shown in FIG. **4***a*. The encapsulation layer **410** is used to protect the sensing matrix **220** to prevent sensing matrix **220** from being damaged during following processes. In this embodiment, the encapsulation layer **410** is formed by using a peelable sealant, but embodiments of the present invention are not limited thereto.

[0032] The encapsulating step 320 is performed between the combination step 130 and the slimming step 140. The encapsulating step 320 is performed before the slimming step 140 to form an encapsulation layer 420 on side surfaces of the touch-sensing liquid crystal panel to protect the side surfaces of the touch-sensing liquid crystal panel, as shown in FIG. 4b. The encapsulation layer 420 is used to protect the side surfaces of the touch-sensing liquid crystal panel to prevent the side surfaces of the touch-sensing liquid crystal panel from being damaged during following processes. The encapsulation layer 420 is formed by using a peelable sealant, but embodiments of the present invention are not limited thereto. [0033] It can be understood from the above descriptions that the fabrication method 300 of the touch-sensing liquid crystal panel uses the encapsulating steps 312 and 320 to form the encapsulation layers 410 and 420 to prevent the side surfaces of the touch-sensing liquid crystal panel from being damaged by the slimming step 140. The fabrication method 300 of the touch-sensing liquid crystal panel not only simplifies the production process of the touch-sensing liquid crystal panel but also follows design standards of thin-film transistors, so as to provide a more reliable touch-sensing liquid crystal panel.

[0034] It will be apparent to those skilled in the art that various modifications and variations can be made to the structure of the present invention without departing from the scope or spirit of the invention. In view of the foregoing, it is intended that the present invention cover modifications and variations of this invention provided they fall within the scope of the following claims and their equivalents.

What is claimed is:

1. A touch-sensing liquid crystal panel, comprising:

a color filter substrate, comprising:

- a first glass substrate having a first surface and a second surface, wherein the first surface is opposite to the second surface;
- a sensing matrix disposed on the first surface of the first glass substrate, wherein the sensing matrix is formed from indium tin oxide (ITO), and the sensing matrix has a sheet resistance smaller than or equal to 30 ohm/square;
- a plurality of color filters disposed on the second surface of the first glass substrate; and

a transistor substrate, comprising:

- a second glass substrate having a thickness smaller than or equal to 0.2 mm; and
- a pixel layer disposed on the second glass substrate, wherein the pixel layer comprises a plurality of pixel units, and each of the pixel units comprises a switching transistor and a pixel electrode; and
- a liquid crystal layer disposed between the color filter substrate and the transistor substrate.

2. The touch-sensing liquid crystal panel of claim **1**, wherein the sensing matrix has a thickness ranging from 600 Angstroms to 1400 Angstroms.

3. The touch-sensing liquid crystal panel of claim 1, wherein the sensing matrix is formed by a baking operation at a baking temperature greater than 230° C.

4. The touch-sensing liquid crystal panel of claim **1**, further comprises an encapsulation layer located on the sensing matrix for protecting the sensing matrix.

5. The touch-sensing liquid crystal panel of claim **1**, further comprises an encapsulation layer located on a plurality of side surfaces of the color filter substrate and the transistor substrate for protecting the side surfaces.

6. The touch-sensing liquid crystal panel of claim 1, wherein the sensing matrix has a pattern of lines crossing each other.

7. A touch-sensing liquid crystal panel, comprising:

- a color filter substrate, comprising:
 - a first glass substrate having a first surface and a second surface, wherein the first surface is opposite to the second surface;
 - a sensing matrix disposed on the first surface of the first glass substrate, wherein the sensing matrix is formed from indium tin oxide (ITO), and the sensing matrix has a sheet resistance smaller than or equal to 30 ohm/square;
 - a plurality of color filters disposed on the second surface of the first glass substrate; and

a transistor substrate, comprising:

- a second glass substrate treated by a slimming process; and
- a pixel layer disposed on the second glass substrate, wherein the pixel layer comprises a plurality of pixel units, and each of the pixel units comprises a switching transistor and a pixel electrode; and
- a liquid crystal layer disposed between the color filter substrate and the transistor substrate.

8. The touch-sensing liquid crystal panel of claim 7, wherein the sensing matrix has a thickness ranging from 600 Angstroms to 1400 Angstroms.

9. The touch-sensing liquid crystal panel of claim 7, wherein the sensing matrix is formed by a baking operation at a baking temperature greater than 230° C.

10. The touch-sensing liquid crystal panel of claim **7**, further comprises an encapsulation layer located on the sensing matrix for protecting the sensing matrix.

11. The touch-sensing liquid crystal panel of claim 7, further comprises an encapsulation layer located on a plurality of side surfaces of the color filter substrate and the transistor substrate for protecting the side surfaces.

12. The touch-sensing liquid crystal panel of claim 7, wherein the sensing matrix has a pattern of lines crossing each other.

13. A touch-sensing liquid crystal panel, comprising:

a color filter substrate, comprising:

- a first glass substrate having a first surface and a second surface, wherein the first surface is opposite to the second surface;
- a sensing matrix disposed on the first surface of the first glass substrate, wherein the sensing matrix is formed from indium tin oxide (ITO), and the sensing matrix has a sheet resistance smaller than or equal to 30 ohm/square;
- a plurality of color filters disposed on the second surface of the first glass substrate; and

a transistor substrate, comprising:

a second glass substrate; and

- a pixel layer disposed on the second glass substrate, wherein the pixel layer comprises a plurality of pixel units, and each of the pixel units comprises a switching transistor and a pixel electrode; and
- a liquid crystal layer disposed between the color filter substrate and the transistor substrate.

14. The touch-sensing liquid crystal panel of claim 13, wherein the sensing matrix has a thickness ranging from 600 Angstroms to 1400 Angstroms.

15. The touch-sensing liquid crystal panel of claim 13, wherein the sensing matrix is formed by a baking operation at a baking temperature greater than 230° C.

16. The touch-sensing liquid crystal panel of claim 13, further comprises an encapsulation layer located on the sensing matrix for protecting the sensing matrix.

17. The touch-sensing liquid crystal panel of claim **13**, further comprises an encapsulation layer located on a plurality of side surfaces of the color filter substrate and the transistor substrate for protecting the side surfaces.

18. The touch-sensing liquid crystal panel of claim 13, wherein the sensing matrix has a pattern of lines crossing each other.
