(57) **ABSTRACT**

Disclosed are antenna systems and related methods. An antenna system includes one or more feeds configured to receive an electromagnetic (EM) signal and propagate the EM signal as an EM reference wave. The antenna system also includes a plurality of tunable EM scattering elements spaced at sub-wavelength distances, and a controller operably coupled to the plurality of tunable EM scattering elements. A method includes operating the plurality of tunable EM scattering elements in at least two different operational states to selectively scatter the EM reference wave as a radiated wave, and modulating the radiated wave over time to deliver a plurality of different information streams to a plurality of different far-end locations by modulating the plurality of tunable EM scattering elements between the plurality of different operational states over time.

MASSIVELY MULTI-USER MIMO USING SPACE TIME HOLOGRAPHY

[0001] If an Application Data Sheet (ADS) has been filed on the filing date of this application, it is incorporated by reference herein. Any applications claimed on the ADS for priority under 35 U.S.C. §§119, 120, 121, or 365(c), and any and all parent, grandparent, great-grandparent, etc. applications of such applications, are also incorporated by reference, including any priority claims made in those applications and any material incorporated by reference, to the extent such subject matter is not inconsistent herewith.

CROSS-REFERENCE TO RELATED APPLICATIONS

[0002] The present application claims the benefit of the earliest available effective filing date(s) from the following listed application(s) (the "Priority Applications"), if any, listed below (e.g., claims earliest available priority dates for other than provisional patent applications or claims benefits under 35 USC §119(e) for provisional patent applications, for any and all parent, grandparent, great-grandparent, etc. applications of the Priority Application(s)).

PRIORITY APPLICATIONS

[0003] This application claims priority to U.S. Provisional Patent Application No. 62/357,754 to Eric J. Black et al., titled MASSIVELY MULTI-USER MIMO USING SPACE-TIME HOLOGRAPHY, and filed Jul. 1, 2016, the entire disclosure of which is hereby incorporated herein by this reference.

[0004] If the listings of applications provided above are inconsistent with the listings provided via an ADS, it is the intent of the Applicant to claim priority to each application that appears in the Domestic Benefit/National Stage Information section of the ADS and to each application that appears in the Priority Applications section of this application.

[0005] All subject matter of the Priority Applications and of any and all applications related to the Priority Applications by priority claims (directly or indirectly), including any priority claims made and subject matter incorporated by reference therein as of the filing date of the instant application, is incorporated herein by reference to the extent such subject matter is not inconsistent herewith.

BRIEF DESCRIPTION OF THE FIGURES

[0006] FIG. 1 is a simplified block diagram of an antenna system.

[0007] FIG. 2 is a simplified flowchart illustrating a method of operating the antenna system of FIG. 1.

[0008] FIG. 3 is a simplified block diagram of a controller of the antenna system of FIG. 1.

DETAILED DESCRIPTION

[0009] In the following detailed description, reference is made to the accompanying drawings, which form a part hereof. In the drawings, similar symbols typically identify similar components, unless context dictates otherwise. The illustrative embodiments described in the detailed description, drawings, and claims are not meant to be limiting. Other embodiments may be utilized, and other changes may be made, without departing from the spirit or scope of the subject matter presented herein.

[0010] Embodiments of the disclosure include antenna systems and related methods for generating modulated signals by modulating electromagnetic (EM) scattering elements rather than by modulating EM signals fed to the EM scattering elements.

[0011] Various features disclosed herein may be applied alone or in combination with others of the features disclosed herein. These features are too numerous to explicitly indicate herein each and every other one of the features that may be combined therewith. Therefore, any feature disclosed herein that is practicable, in the view of one of ordinary skill, to combine with any other one or more others of the features disclosed herein, is contemplated herein to be combined. A non-exhaustive list of some of these disclosed features that may be combined with others of the disclosed features follows.

[0012] For example, in some embodiments, an antenna system comprises: one or more feeds configured to receive an electromagnetic (EM) signal and propagate the EM signal as an EM reference wave; a plurality of tunable EM scattering elements spaced at sub-wavelength distances, the plurality of tunable EM scattering elements configured to operate in at least two different operational states to selectively scatter the EM reference wave as a radiated wave; and control circuitry comprising a controller operably coupled to the plurality of tunable EM scattering elements and programmed to modulate the radiated wave over time to deliver a plurality of different information streams to a plurality of different far-end locations by modulating the plurality of tunable EM scattering elements between the plurality of different operational states over time.

[0013] In some embodiments, an antenna system includes one or more feeds configured to receive a monochromatic continuous wave EM signal.

[0014] In some embodiments, an antenna system includes one or more feeds configured to receive a modulated EM signal.

[0015] In some embodiments, an antenna system includes a controller programmed to control tunable EM scattering elements through control lines.

[0016] In some embodiments, an antenna system includes a controller programmed to control each of the tunable EM scattering elements individually through a separate control line.

[0017] In some embodiments, an antenna system includes a controller programmed to control each of tunable EM scattering elements individually through a combination of signals from at least two separate control lines.

[0018] In some embodiments, an antenna system includes control lines, wherein each of the control lines is isolated and decoupled from each of the other control lines.

[0019] In some embodiments, an antenna system includes a plurality of high frequency EM transmission lines operably coupling a controller to a plurality of tunable EM scattering elements, wherein the plurality of high-frequency EM transmission lines is configured to transmit EM waves having a frequency of at least about twice a frequency of a reference wave.

[0020] In some embodiments, an antenna system includes a plurality of high-frequency EM transmission lines including a plurality of optical transmission lines, and a plurality of tunable EM scattering elements including a plurality of

optically tunable EM scattering elements tunable by optical signals transmitted through the plurality of optical transmission lines.

[0021] In some embodiments, an antenna system includes a plurality of optical transmission lines including a plurality of optical fibers.

[0022] In some embodiments, an antenna system includes a plurality of optically tunable EM scattering elements comprising a plurality of photodiodes.

[0023] In some embodiments, an antenna system includes a plurality of optically tunable EM scattering elements comprising a plurality of phototransistors.

[0024] In some embodiments, an antenna system includes a plurality of optically tunable EM scattering elements comprising a plurality of photoconductive or photoresistive elements.

[0025] In some embodiments, an antenna system includes a plurality of optically tunable EM scattering elements comprising a plurality of phase-change elements configured to change phase responsive to heat deposition of optical radiation.

[0026] In some embodiments, an antenna system includes a controller programmed to modulate a plurality of optically tunable EM scattering elements at a frequency of at least about one (1) gigahertz.

[0027] In some embodiments, an antenna system includes a controller programmed to modulate a plurality of optically tunable EM scattering elements at a time scale that is longer than a time that it takes for a radiated wave to travel from the plurality of optically tunable EM scattering elements to a plurality of different far-end locations.

[0028] In some embodiments, an antenna system includes a controller programmed to modulate a plurality of optically tunable EM scattering elements as a temporal series of modulation patterns, wherein each modulation pattern of the series is determined by solving a time invariant holographic projection manifold function.

[0029] In some embodiments, an antenna system includes a controller programmed to solve a time invariant holographic projection manifold function using a Green's function.

[0030] In some embodiments disclosed is an antenna system including a controller programmed to modulate a plurality of optically tunable EM scattering elements at a time scale that is shorter than a time that it takes for a radiated wave to travel from a plurality of optically tunable EM scattering elements to a plurality of different far-end locations.

[0031] In some embodiments, disclosed is an antenna system, wherein a controller is programmed to modulate a plurality of optically tunable EM scattering elements as a series of modulation patterns, wherein at least a portion of the modulation patterns of the series is determined by solving a time variant holographic projection manifold function.

[0032] In some embodiments, an antenna system includes a controller programmed to solve a time variant holographic projection manifold function using a retarded Green's function.

[0033] In some embodiments, two or more different operational states of a plurality of optically tunable EM scattering elements of an antenna system comprise more than two operational states.

[0034] In some embodiments, an antenna system includes a controller programmed to transition the antenna system between different holograms gradually.

[0035] In some embodiments, an antenna system includes a controller programmed to transition between different holograms by smoothing control signals delivered to a plurality of optically tunable EM scattering elements with smoothed Heaviside functions.

[0036] In some embodiments, an antenna system includes a controller programmed to transition between different holograms by smoothing control signals delivered to a plurality of optically tunable EM scattering elements with piecewise-trigonometric functions.

[0037] In some embodiments, an antenna system includes a controller programmed to transition between different holograms by smoothing control signals delivered to a plurality of optically tunable EM scattering elements with spline polynomial functions.

[0038] In some embodiments, an antenna system includes a controller programmed to modulate a radiated wave over time to deliver a plurality of different frequency modulated information streams to a plurality of different far-end locations.

[0039] In some embodiments, an antenna system includes a controller programmed to modulate a radiated wave over time to deliver a plurality of different amplitude modulated information streams to a plurality of different far-end locations.

[0040] In some embodiments, an antenna system includes a controller programmed to modulate a radiated wave over time to deliver a plurality of different phase modulated information streams to a plurality of different far-end locations.

[0041] In some embodiments, an antenna system includes a controller programmed to modulate a radiated wave over time to deliver a plurality of different quadrature amplitude modulated (QAM) data streams to a plurality of different far-end locations.

[0042] In some embodiments, an antenna system includes a controller programmed to modulate a radiated wave over time to deliver a plurality of different analog modulated information streams to a plurality of different far-end locations.

[0043] In some embodiments, an antenna system includes a controller programmed to modulate a radiated wave over time to deliver a plurality of different digital modulated data streams to a plurality of different far-end locations.

[0044] In some embodiments, an antenna system includes a controller programmed to modulate a radiated wave over time to deliver a plurality of different spread-spectrum modulated data streams to a plurality of different far-end locations.

[0045] In some embodiments, an antenna system includes a waveguide and a plurality of optically tunable EM scattering elements, which together comprise a metamaterial.

[0046] In some embodiments, at least some far-end locations of an antenna system coincide with EM receivers.

[0047] In some embodiments, at least two EM receivers of an antenna system comprise multiple input, multiple output (MIMO) receiver devices.

[0048] In some embodiments, at least two groups of at least two EM receivers of an antenna system comprise MIMO receiver devices.

[0049] In some embodiments, at least two EM receivers of an antenna system belong to two physically separate receiver devices.

[0050] In some embodiments, at least two groups of EM receivers of an antenna system, each having at least two receivers, belong to two physically separate receiver devices.

[0051] In some embodiments, an antenna system comprises a plurality of acoustic transmission lines operably coupling a controller to a plurality of tunable EM scattering elements, and the plurality of tunable EM scattering elements includes a plurality of acoustically tunable EM scattering elements tunable by acoustic signals transmitted through the plurality of acoustic transmission lines.

[0052] In some embodiments, a plurality of acoustically tunable EM scattering elements of an antenna system includes piezoelectric elements.

[0053] In some embodiments, a plurality of acoustically tunable EM scattering elements of an antenna system includes magnetostrictive elements.

[0054] In some embodiments, a plurality of acoustically tunable EM scattering elements of an antenna system includes microelectromechanical (MEM) elements.

[0055] In some embodiments, an antenna system includes a controller programmed to modulate a plurality of acoustically tunable EM scattering elements at a frequency of at least about one (1) gigahertz.

[0056] In some embodiments, an antenna system includes a controller programmed to modulate a plurality of acoustically tunable EM scattering elements at a time scale that is longer than a time that it takes for a radiated wave to travel from the plurality of acoustically tunable EM scattering elements to a plurality of different far-end locations.

[0057] In some embodiments, an antenna system includes a controller programmed to modulate a plurality of acoustically tunable EM scattering elements as a temporal series of modulation patterns, wherein each modulation pattern of the series is determined by solving a time invariant holographic projection manifold function.

[0058] In some embodiments, an antenna system includes a controller programmed to solve a time invariant holographic projection manifold functions using a Green's function.

[0059] In some embodiments, an antenna system includes a controller programmed to modulate a plurality of acoustically tunable EM scattering elements at a time scale that is shorter than a time that it takes for a radiated wave to travel from the plurality of acoustically tunable EM scattering elements to a plurality of different far-end locations.

[0060] In some embodiments, an antenna system includes a controller programmed to modulate a plurality of acoustically tunable EM scattering elements as a series of modulation patterns, wherein at least a portion of the modulation patterns of the series is determined by solving a time variant holographic projection manifold function.

[0061] In some embodiments, an antenna system includes a controller programmed to solve a time variant holographic projection manifold function using a retarded Green's function.

[0062] In some embodiments, two or more different operational states of each of a plurality of acoustically tunable EM scattering elements of an antenna system comprises more than two operational states.

[0063] In some embodiments, an antenna system includes a controller programmed to transition the antenna system between different holograms gradually.

[0064] In some embodiments, an antenna system includes a controller programmed to transition between different holograms by smoothing control signals delivered to a plurality of acoustically tunable EM scattering elements with smoothed Heaviside functions.

[0065] In some embodiments, an antenna system includes a controller programmed to transition between different holograms by smoothing control signals delivered to a plurality of acoustically tunable EM scattering elements with piecewise-trigonometric functions.

[0066] In some embodiments, an antenna system includes a controller programmed to transition between different holograms by smoothing control signals delivered to a plurality of acoustically tunable EM scattering elements with spline polynomial functions.

[0067] In some embodiments, an antenna system includes a controller programmed to modulate a radiated wave over time to deliver a plurality of different frequency modulated information streams to a plurality of different far-end locations.

[0068] In some embodiments, an antenna system includes a controller programmed to modulate a radiated wave over time to deliver a plurality of different amplitude modulated information streams to a plurality of different far-end locations.

[0069] In some embodiments, an antenna system includes a controller programmed to modulate a radiated wave over time to deliver a plurality of different phase modulated information streams to a plurality of different far-end locations.

[0070] In some embodiments, an antenna system includes a controller programmed to modulate a radiated wave over time to deliver a plurality of different quadrature amplitude modulated (QAM) data streams to the plurality of different far-end locations.

[0071] In some embodiments, an antenna system includes a controller programmed to modulate a radiated wave over time to deliver a plurality of different analog modulated information streams to the plurality of different far-end locations.

[0072] In some embodiments, an antenna system includes a controller programmed to modulate a radiated wave over time to deliver a plurality of different digital modulated data streams to the plurality of different far-end locations.

[0073] In some embodiments, an antenna system includes a controller programmed to modulate a radiated wave over time to deliver a plurality of different spread-spectrum modulated data streams to a plurality of different far-end locations.

[0074] In some embodiments, an antenna system includes a waveguide and a plurality of acoustically tunable EM scattering elements, which together comprise a metamaterial.

[0075] In some embodiments, at least some far-end locations of an antenna system coincide with EM receivers.

[0076] In some embodiments, an antenna system includes at least two EM receivers comprising multiple input, multiple output (MIMO) receiver devices.

[0077] In some embodiments, at least two groups of at least two EM receivers of an antenna system comprise MIMO receiver devices.

[0078] In some embodiments, at least two EM receivers of an antenna system belong to two physically separate receiver devices.

[0079] In some embodiments, at least two groups of EM receivers each having at least two receivers of an antenna system belong to two physically separate receiver devices.

[0080] In some embodiments, a method of operating an antenna system comprises: receiving and propagating an electromagnetic (EM) signal as an EM reference wave with one or more feeds; operating a plurality of tunable EM scattering elements spaced at sub-wavelength distances in at least two different operational states to selectively scatter the EM reference wave as a radiated wave; and modulating the radiated wave over time to deliver a plurality of different information streams to a plurality of different far-end locations by modulating the plurality of tunable EM scattering elements between the plurality of different operational states over time.

[0081] In some embodiments, receiving and propagating an EM signal comprises receiving and propagating a monochromatic continuous wave EM signal.

[0082] In some embodiments, receiving and propagating an EM signal comprises receiving and propagating a modulated EM signal.

[0083] In some embodiments, operating a plurality of tunable EM scattering elements comprises controlling the tunable EM scattering elements through control lines.

[0084] In some embodiments, modulating a plurality of tunable EM scattering elements comprises controlling each of the tunable EM scattering elements individually through a separate control line.

[0085] In some embodiments, operating a plurality of tunable EM scattering elements comprises controlling each of the tunable EM scattering elements individually through a combination of signals from at least two separate control lines.

[0086] In some embodiments, modulating a plurality of tunable EM scattering elements comprises controlling the tunable EM scattering elements through control lines isolated and decoupled from each of the others of the control lines.

[0087] In some embodiments, controlling a plurality of tunable EM scattering elements through the control lines comprises controlling the plurality of tunable EM scattering elements using a plurality of high frequency EM transmission lines, and using the plurality of high-frequency EM transmission lines to transmit EM waves having a frequency of at least about twice a frequency of the reference wave.

[0088] In some embodiments, controlling a plurality of tunable EM scattering elements using a plurality of high frequency EM transmission lines includes controlling the plurality of tunable EM scattering elements using a plurality of optical transmission lines, and wherein the plurality of tunable EM scattering elements includes a plurality of optically tunable EM scattering elements tunable by optical signals transmitted through the plurality of optical transmission lines.

[0089] In some embodiments, controlling a plurality of optically tunable EM scattering elements using a plurality of optical transmission lines comprises controlling the plurality of optically tunable EM scattering elements using a plurality of optical fibers.

[0090] In some embodiments, controlling a plurality of optically tunable EM scattering elements comprises controlling a plurality of photodiodes.

[0091] In some embodiments, controlling a plurality of optically tunable EM scattering elements comprises controlling a plurality of phototransistors.

[0092] In some embodiments, controlling a plurality of optically tunable EM scattering elements comprises controlling a plurality of photoconductive or photoresistive elements.

[0093] In some embodiments, controlling a plurality of optically tunable EM scattering elements comprises controlling a plurality of phase-change elements configured to change state responsive to heat deposition of optical radiation.

[0094] In some embodiments, controlling a plurality of optically tunable EM scattering elements comprises modulating the plurality of optically tunable EM scattering elements at a frequency of at least about one (1) gigahertz.

[0095] In some embodiments, controlling a plurality of optically tunable EM scattering elements comprises modulating the plurality of optically tunable EM scattering elements at a time scale that is longer than a time that it takes for a radiated wave to travel from the plurality of optically tunable EM scattering elements to a plurality of different far-end locations.

[0096] In some embodiments, modulating a plurality of optically tunable EM scattering elements comprises modulating the plurality of optically tunable EM scattering elements as a temporal series of modulation patterns, wherein each modulation pattern of the series is determined by solving a time invariant holographic projection manifold function.

[0097] In some embodiments, solving a time invariant holographic projection manifold function comprises solving the time invariant holographic projection manifold functions using a Green's function.

[0098] In some embodiments, controlling a plurality of optically tunable EM scattering elements comprises modulating the plurality of optically tunable EM scattering elements at a time scale that is shorter than a time that it takes for a radiated wave to travel from the plurality of optically tunable EM scattering elements to a plurality of different far-end locations.

[0099] In some embodiments, modulating a plurality of optically tunable EM scattering elements comprises modulating the plurality of optically tunable EM scattering elements as a series of modulation patterns, wherein at least a portion of the modulation patterns of the series is determined by solving a time variant holographic projection manifold function.

[0100] In some embodiments, modulating a plurality of optically tunable EM scattering elements as a series of modulation patterns comprises solving a time variant holographic projection manifold function using a retarded Green's function.

[0101] In some embodiments, operating a plurality of tunable EM scattering elements in at least two different operational states comprises operating the plurality of tunable EM scattering elements in more than two operational states.

[0102] In some embodiments, a method comprises transitioning an antenna system between different holograms gradually.

[0103] In some embodiments, transitioning an antenna system between different holograms gradually comprises transitioning between the different holograms by smoothing control signals delivered to a plurality of optically tunable EM scattering elements with smoothed Heaviside functions.

[0104] In some embodiments, transitioning an antenna system between different holograms gradually comprises transitioning between the different holograms by smoothing control signals delivered to a plurality of optically tunable EM scattering elements with piecewise-trigonometric functions.

[0105] In some embodiments, transitioning an antenna system between different holograms gradually comprises transitioning between the different holograms by smoothing control signals delivered to a plurality of optically tunable EM scattering elements with spline polynomial functions.

[0106] In some embodiments, controlling a plurality of optically tunable EM scattering elements comprises modulating a radiated wave over time to deliver a plurality of different frequency modulated information streams to a plurality of different far end locations.

[0107] In some embodiments, controlling a plurality of optically tunable EM scattering elements comprises modulating a radiated wave over time to deliver a plurality of different amplitude modulated information streams to a plurality of different far end locations.

[0108] In some embodiments, controlling a plurality of optically tunable EM scattering elements comprises modulating a radiated wave over time to deliver a plurality of different phase modulated information streams to a plurality of different far-end locations.

[0109] In some embodiments, controlling a plurality of optically tunable EM scattering elements comprises modulating a radiated wave over time to deliver a plurality of different quadrature amplitude modulated (QAM) data streams to a plurality of different far end locations.

[0110] In some embodiments, controlling a plurality of optically tunable EM scattering elements comprises modulating a radiated wave over time to deliver a plurality of different analog modulated information streams to a plurality of different far end locations.

[0111] In some embodiments, controlling a plurality of optically tunable EM scattering elements comprises modulating a radiated wave over time to deliver a plurality of different digital modulated data streams to a plurality of different far end locations.

[0112] In some embodiments, controlling a plurality of optically tunable EM scattering elements comprises modulating a radiated wave over time to deliver a plurality of different spread-spectrum modulated data streams to a plurality of different far end locations.

[0113] In some embodiments, propagating an electromagnetic (EM) signal as an EM reference wave comprises propagating the EM signal using a metamaterial comprising a waveguide and a plurality of optically tunable EM scattering elements.

[0114] In some embodiments, delivering a plurality of different information streams to a plurality of different far-end locations comprises delivering the plurality of different information streams to at least some of far-end locations coinciding with EM receivers.

[0115] In some embodiments, at least two of EM receivers include multiple input, multiple output (MIMO) devices.

[0116] In some embodiments, delivering a plurality of different information streams to at least some of far-end locations coinciding with EM receivers comprises delivering the plurality of different information streams to at least two groups of at least two EM receivers comprising MIMO receiver devices.

[0117] In some embodiments, delivering a plurality of different information streams to at least some of far-end locations coinciding with EM receivers comprises delivering the plurality of different information streams to at least two EM receivers belonging to two physically separate receiver devices.

[0118] In some embodiments, delivering a plurality of different information streams to at least some of far-end locations coinciding with EM receivers comprises delivering the plurality of different information streams to at least two groups of EM receivers, each having at least two receivers belonging to two physically separate receiver devices.

[0119] In some embodiments, controlling a plurality of tunable EM scattering elements with control lines includes controlling the tunable EM scattering elements using a plurality of acoustic transmission lines, and wherein the plurality of tunable EM scattering elements includes a plurality of acoustically tunable EM scattering elements tunable by acoustic signals transmitted through the plurality of acoustic transmission lines.

[0120] In some embodiments, controlling a plurality of acoustically tunable EM scattering elements comprises controlling a plurality of piezoelectric elements.

[0121] In some embodiments, controlling a plurality of acoustically tunable EM scattering elements comprises controlling magnetostrictive elements.

[0122] In some embodiments, controlling a plurality of acoustically tunable EM scattering elements comprises controlling microelectromechanical (MEM) elements.

[0123] In some embodiments, controlling a plurality of acoustically tunable EM scattering elements comprises modulating the plurality of acoustically tunable EM scattering elements at a frequency of at least about one (1) gigahertz.

[0124] In some embodiments, controlling a plurality of acoustically tunable EM scattering elements comprises modulating the plurality of acoustically tunable EM scattering elements at a time scale that is longer than a time that it takes for a radiated wave to travel from the plurality of acoustically tunable EM scattering elements to a plurality of different far-end locations.

[0125] In some embodiments, modulating a plurality of acoustically tunable EM scattering elements comprises modulating the plurality of acoustically tunable EM scattering elements as a temporal series of modulation patterns, wherein each modulation pattern of the series is determined by solving a time invariant holographic projection manifold function.

[0126] In some embodiments, solving a time invariant holographic projection manifold function comprises solving the time invariant holographic projection manifold functions using a Green's function.

[0127] In some embodiments, controlling a plurality of acoustically tunable EM scattering elements comprises modulating the plurality of acoustically tunable EM scattering elements at a time scale that is shorter than a time that

it takes for a radiated wave to travel from the plurality of acoustically tunable EM scattering elements to a plurality of different far-end locations.

[0128] In some embodiments, modulating a plurality of acoustically tunable EM scattering elements comprises modulating the plurality of acoustically tunable EM scattering elements as a series of modulation patterns, wherein at least a portion of the modulation patterns of the series is determined by solving a time variant holographic projection manifold function.

[0129] In some embodiments, modulating a plurality of acoustically tunable EM scattering elements as a series of modulation patterns comprises solving a time variant holographic projection manifold function using a retarded Green's function.

[0130] In some embodiments, operating a plurality of tunable EM scattering elements in at least two different operational states comprises operating the plurality of tunable EM scattering elements in more than two operational states.

[0131] In some embodiments, transitioning an antenna system between different holograms gradually.

[0132] In some embodiments, transitioning an antenna system between different holograms gradually comprises transitioning between the different holograms by smoothing control signals delivered to a plurality of acoustically tunable EM scattering elements with smoothed Heaviside functions.

[0133] In some embodiments, transitioning an antenna system between different holograms gradually comprises transitioning between the different holograms by smoothing control signals delivered to a plurality of acoustically tunable EM scattering elements with piecewise-trigonometric functions.

[0134] In some embodiments, transitioning an antenna system between different holograms gradually comprises transitioning between the different holograms by smoothing control signals delivered to a plurality of acoustically tunable EM scattering elements with spline polynomial functions.

[0135] In some embodiments, controlling a plurality of acoustically tunable EM scattering elements comprises modulating a radiated wave over time to deliver a plurality of different frequency modulated information streams to a plurality of different far-end locations.

[0136] In some embodiments, controlling a plurality of acoustically tunable EM scattering elements comprises modulating a radiated wave over time to deliver a plurality of different amplitude modulated information streams to a plurality of different far-end locations.

[0137] In some embodiments, controlling a plurality of acoustically tunable EM scattering elements comprises modulating a radiated wave over time to deliver a plurality of different phase modulated information streams to a plurality of different far-end locations.

[0138] In some embodiments, controlling a plurality of acoustically tunable EM scattering elements comprises modulating a radiated wave over time to deliver a plurality of different quadrature amplitude modulated (QAM) data streams to a plurality of different far-end locations.

[0139] In some embodiments, controlling a plurality of acoustically tunable EM scattering elements comprises modulating a radiated wave over time to deliver a plurality

of different analog modulated information streams to a plurality of different far-end locations.

[0140] In some embodiments, controlling a plurality of acoustically tunable EM scattering elements comprises modulating a radiated wave over time to deliver a plurality of different digital modulated data streams to a plurality of different far-end locations.

[0141] In some embodiments, controlling a plurality of acoustically tunable EM scattering elements comprises modulating a radiated wave over time to deliver a plurality of different spread-spectrum modulated data streams to a plurality of different far-end locations.

[0142] In some embodiments, propagating an electromagnetic (EM) signal as an EM reference wave comprises propagating the EM signal using a metamaterial comprising a waveguide and a plurality of acoustically tunable EM scattering elements.

[0143] In some embodiments, delivering a plurality of different information streams to a plurality of different far-end locations comprises delivering the plurality of different information streams to at least some of far-end locations coinciding with EM receivers.

[0144] In some embodiments, delivering a plurality of different information streams to at least some of far-end locations coinciding with EM receivers comprises delivering the plurality of different information streams to at least two of the EM receivers comprising multiple input, multiple output (MIMO) receiver devices.

[0145] In some embodiments, delivering a plurality of different information streams to at least some of far-end locations coinciding with EM receivers comprises delivering the plurality of different information streams to at least two groups of at least two EM receivers comprising MIMO receiver devices.

[0146] In some embodiments, delivering a plurality of different information streams to at least some of far-end locations coinciding with EM receivers comprises delivering the plurality of different information streams to at least two EM receivers belonging to two physically separate receiver devices.

[0147] In some embodiments, delivering a plurality of different information streams to at least some of far-end locations coinciding with EM receivers comprises delivering the plurality of different information streams to at least two groups of EM receivers, each having at least two receivers belonging to two physically separate receiver devices.

[0148] The disclosure relates to various applications of adaptive antenna arrays, in particular those based on Metamaterial Surface Scattering Technology (MSA-T). The disclosure also relates to other antenna systems, including, for example, power transmission antenna systems. Any other systems where transmission, receiving, or a combination thereof, of EM waves is made may benefit from teachings of the disclosure.

[0149] In antennas based on Metamaterial Surface Antenna Technology (MSA-T), coupling between a guided wave and propagating wave is achieved by modulating an impedance of a surface in electromagnetic contact with the guided wave. This controlled surface impedance is referred to as a "Modulation Pattern." The guided wave in the antenna is referred to as a "Reference Wave" or "Reference Mode," and a desired free space propagating wave pattern is referred to as a "Radiated Wave" or "Radiated Mode."

7

[0150] The general method for calculating the modulation pattern for MSA-T antennas is derived from holographic principles. In holography, the surface modulation function is a hologram (ψ_{hol}) formed by a beat of the reference wave (E_{ref}) and the desired radiated wave (E_{rad}). This relationship can be expressed compactly as:

$$\psi_{hol} = \frac{E^*_{ref} E_{rad}}{|E_{ref}|^2}. \qquad [1]$$

Equation [1] suggests that the optimal modulation function depends on the accuracy to which the radiated wave and reference wave are known.

[0151] MSA-T antennas include arrays of discrete radiating elements with element spacing less than one wavelength (e.g., less than one quarter wavelength) at the operating frequency. Radiation from each radiating element can be discretely modulated such that a collective effect approximates a desired modulation pattern.

[0152] As used herein, the term "metamaterials," include their bulk (volumetric, multi-layer, 3D) version, and a single-layer version (sometimes referred to as "metasurfaces"). Metamaterials can be used as electromagnetic holograms, both in the far field and a radiated near field. As used herein, the term "holographic projection," refers to a field distribution created in a selected plane, surface or volume by a remote field source and a remote hologram. A holographic projection can be viewed mathematically as a mapping between a source pattern and a field distribution observed in a select manifold (2D or 3D):

$$\{E_{hologram}(x_i)\} \rightarrow \{E_{observed}(x'_j)\}, \qquad [2]$$

where $x_i \in \Omega_{hologram}$ are selected points within the hologram manifold, and $x'_j \in \Omega_{observed}$ are selected points within the observation manifold. The bold face indicates three-dimensional vectors. This can also be written as a holographic projection functional:

$$E_{observed}(x')=P[E_{hologram}(x)]. \qquad [3]$$

[0153] Some scientific literature adopts the notion that a hologram is of lower dimension than the manifold where the fields are created, leaving in reality only an option of projecting from a 2D surface into a 3D volume. In optics, however, it is widely accepted that holograms can be either thin (e.g., quasi-2D) or thick (e.g., volumetric), and the observation manifold can be either in the far-field (e.g., on a 2D sphere) or on the radiated near field (e.g., 3D). These latter, more general notions of holographic projections and holograms are adopted herein.

[0154] As used herein, the term "hologram" refers to a scattering and/or radiating medium, such as a metamaterial (including, by implication, a metasurface), which generates a holographic projection when properly excited with an intended field source. A hologram and a field source can be co-located or even intertwined, or they can be separated by a distance. Holograms based on tunable and/or active metamaterials can change as a function of time, based on a time-dependent actuation of the tunable elements and/or power sources embedded within such metamaterials. The same applies to adaptive antenna arrays, a class of radiating structures that overlaps architecturally and functionally with tunable/active metamaterials.

[0155] As used herein, the term "monochromatic" refers to a single EM frequency. For example, a "monochromatic signal" refers to an EM signal having a single frequency (e.g., a simple sinusoidal, continuous wave EM signal).

[0156] Adaptive antenna arrays, as well as tunable/active metamaterials, derive their response from two distinct sources: a feed(s) and control lines. Typically, the feed is either a waveguide or transmission line, or a network of transmission lines. The feed could also be a plane wave or another field distribution generated remotely, such as in dish and other reflector antennas (e.g., adaptive reflect-arrays). The feed delivers the majority or all of the power radiated by the adaptive antenna array. The control lines, on the contrary, typically do not deliver any substantial amount of power. Rather, the control lines are typically used to modulate the amount of power and the characteristics of electromagnetic radiation emitted from the antenna elements. The standard paradigm in adaptive antenna arrays, including phased arrays and MSA-T antennas, was to modulate the feed with frequencies contained in a selected radio frequency (RF) or microwave band, using the control lines only for beam pattern modulation on a relatively slow time scale. Under this approach, any and all receivers of signals from such an adaptive antenna array receive essentially the same information. While this is useful for broadcasting, this technique is incapable of creating multiple independent communication channels or information streams, which would be useful in a multi-user communications system (e.g., multi-user multiple input, multiple output (MU-MIMO)).

[0157] Disclosed herein are antenna systems and related methods that use time-dependence of control signals to generate time-dependent holographic projections, and that use those holographic projections to conduct wireless transmissions of information. In this way, a theoretical maximum throughput in a bandwidth-constrained and volume-constrained multi-user communication system may approach the theoretical maximum throughput in a bandwidth-constrained and volume-constrained multi-user communication system. In some embodiments, these antenna systems and methods provide a monochromatic or otherwise fixed-spectrum field to the tunable/adaptive radiating elements, and the control lines perform modulation to insert information into a wireless signals. In some embodiments, these antenna systems and methods can be combined with a time-dependent (modulated) feed.

[0158] FIG. 1 is a simplified block diagram of an antenna system 100 according to some embodiments. The antenna system 100 includes one or more feeds 110 configured to receive EM signals 102 (e.g., one or more EM signals 102) and propagate an EM reference wave 112 to a plurality of tunable EM scattering elements 120 of the antenna system 100. The plurality of tunable EM scattering elements 120 are spaced at sub-wavelength distances (e.g., at less than or equal to about a half wavelength of an operational frequency, at less than or equal to a quarter wavelength of the operational frequency, etc.). The plurality of tunable EM scattering elements 120 are configured to operate in at least two different operational states (e.g., binary and/or grey-scale) to selectively scatter the EM reference wave as a radiated wave 122. As used herein, the term "operational frequency" refers to a fundamental frequency of the radiated wave in freespace (e.g., through the air).

[0159] The antenna system 100 also includes control circuitry 130 including a controller 132 operably coupled to the

8

plurality of tunable EM scattering elements **120** by a plurality of control lines **134**. The controller **132** is programmed to modulate the radiated wave **122** over time to deliver a plurality of different information streams to a plurality of different far-end locations **140** by modulating the plurality of tunable EM scattering elements **120** between the plurality of different operational states over time. In other words, an information stream from the radiated wave **122** received at some of the different far-end locations **140** may be different from an information stream from the radiated wave **122** received at others of the different far-end locations. As used herein, the term "information stream" refers to digital information streams (e.g., data streams), analog information streams, or combinations thereof.

[0160] In some embodiments, the EM signals **102** received by the feeds **110** are unmodulated, monochromatic signals. Accordingly, the modulation that occurs in the radiated wave **122** is responsive to the modulations performed on the tunable scattering elements **120** by the controller **132** through the control lines **134**. In some embodiments, a combination of modulation on the EM signals **102** and the control lines **134** may be used.

[0161] In some embodiments, the antenna system **100** may include an MSA-T antenna system. MSA-T and other adaptive antenna array systems enable the generation of field distributions (i.e., holographic projections) with minimum deviation from a desired field profile, by virtue of selecting parameters of radiating elements (e.g., the tunable scattering elements **120**) within their tenability range. Those parameters are controlled and enforced by control lines (e.g., the control lines **134**). These techniques enable the creation of a desired field profile at any given time t:

$$E_{observed}(x',t')=P[E_{hologram}(x),t=t'-\Delta t], \qquad [4]$$

where t is time at a near-end position where the feeds **110** and tunable scattering elements **120** are located, x is position relative to the near-end location, t' is time seen at one of the far-end locations **140**, x' is position relative to the one of the far-end locations **140**, $E_{observed}$ is an observed electric field at the one of the far-end locations **140**, and $E_{hologram}$ is an electric field at the near-end location.

[0162] Because of finite propagation time, the time $t=t'+\Delta t$ in the left hand side (l.h.s.) of equation 4 is slightly later than the time t in the right hand side (r.h.s.) of equation 4. This difference in time is roughly the time of flight $\Delta t=d/c$, where d is the distance between the hologram and the projection manifold, and c is the speed of light along that path. This mapping can be calculated using a Green's function of electromagnetic fields. This function is particularly simple in the Fourier (plane-wave) representation.

[0163] In this fashion, an adaptive antenna array (e.g., the antenna system **100**) used as a wireless transmitter can simultaneously carry out transmission of a number of different and independent information streams to a number of independent users (i.e., at different far-end locations **140**). Since each user located at a different point x'_j observes (receives) a different electric field, $E_{observed}(x'_j, t)$, the time dependence of this received electric field can be used to transmit information using any of variety of known modulation schemes. The number of users, each having an independent information stream, can be very large because the number is limited only by the number of tunable scattering elements **120** and/or the number of independent control lines **134** coupled to the tunable scattering elements **120**. This

scheme reduces (e.g., eliminates) inter-symbol or inter-channel interference issues, since all of these effects are taken into account as part of the time-dependent hologram calculation. Consequently, in a bandwidth-limited and volume-limited multi-user scenario, which is interference limited, the antenna system **100** enables communication to approach a highest theoretically possible sum-of-throughputs.

[0164] For equation [4] to be accurate without further complications it is assumed that the time of flight is much shorter than the typical modulation time scale for the hologram (or the symbol duration, in terms of wireless communications):

$$\Delta t<<T_{sym}. \qquad [5]$$

For example, for a communication distance of 1 kilometer (km) (a typical scale for macro-cellular communications), this condition of equation [5] limits the modulation rate to about 100,000 frames per second, or 100 kilohertz (kHz). For a communication distance of 10 meters (m) (a typical scale for indoor router usage scenarios), the above condition limits modulation rate to 10 MHz. In this low-modulation-frequency limit, time-dependent holograms can be generated as a series of frames, where the modulation pattern for each frame can be computed using the same algorithms that apply to quasi-static cases.

[0165] In addition, if hardware permits, the transition between the holograms can be continuous (e.g., greyscale as opposed to binary). By way of non-limiting example, transient signals in the control lines **134** can be based, at least in part, on smoothed Heaviside functions, piecewise-trigonometric functions, or spline polynomials.

[0166] For modulation rates exceeding the quasi-static hologram condition (equation [5]), the holographic projection equation becomes fully four-dimensional:

$$E_{observed}(x',t')=P[E_{hologram}(x,t<t')]. \qquad [6]$$

Notation of equation [6] implies that the observed fields depend on the values of $E_{hologram}(x, t)$ at all previous times. Even so, the calculation of the modulation pattern for creating this time-dependent projection can be readily calculated using the standard retarded Green's function. The Liénard-Wiechert potentials are a convenient way to write the retarded Green's function in a way that reflects the physical notion of fields propagating at a constant speed c (about the speed of light) from their various sources to an observation point.

[0167] For the quasi-static case (equation [5]), methods for calculating an optimal control signal distribution for generating a desired hologram in an adaptive antenna array or MSA-T array (e.g., that of the antenna system **100** of FIG. 1) with non-negligible inter-element interaction generalize, in a straightforward fashion, to the time-dependent case. For faster-than-quasistatic modulation, these methods can be extended by including the time variable as an additional dimension. In other words, instead of N variable port impedances, the optimization algorithm must deal with $N \times N_{sym}$ port impedance values at times t_i, i=1, . . . N_{sym}.

[0168] It is implicitly assumed above that the control lines **134** are almost perfectly isolated from one another, as well as from the distributed feed (e.g., from all parts of the distributed feed). While isolation of the control lines **134** is relatively simple to achieve at frame rates in the kHz to a few MHz range, at a sufficiently high modulation frequency mutual coupling between the control lines **134** becomes an

issue. These issues become relatively difficult to deal with at modulation rates in the GHz range or above, limiting the usability of conventional control line architectures to bandwidths of about 100 MHz. Consequently, data rates may cap out at roughly about 100 Mbit/s for mutually coupled control lines **134**.

[0169] While systems with data rates at or below 100 Mbit/s are useful, there is demand for systems, such as the antenna system **100** of FIG. **1**, that are capable of operating in the Gbit/s data rate range. To accommodate such high hologram modulation rates, a different architecture of the control lines **134** is proposed herein. Instead of control lines being electromagnetic and based on RF transmission lines (e.g., electrical conductors or microstrip lines), control lines **134** configured for other types of fields are proposed herein.

[0170] In some embodiments, the control lines **134** operably coupling the controller **132** to the tunable scattering elements **120** are at least substantially electromagnetically isolated from each other. By way of non-limiting example, the control lines **134** may include optical control lines (e.g., fiber optics), acoustic control lines, or combinations thereof. Accordingly, the tunable scattering elements **120** may include optically tunable EM scattering elements, acoustically tunable EM scattering elements, other tunable EM scattering elements, or combinations thereof.

[0171] In embodiments where the control lines **134** include optical control lines, control fields carried by the control lines **134** may be optical. By way of non-limiting example, the control fields may include ultraviolet (UV) fields, visible light fields, infrared fields, far infrared fields, other optical fields, or combinations thereof. Generally speaking, optical fields may include electromagnetic fields with millimeter and shorter wavelengths. Such waves can be tightly confined in optical transmission lines (e.g., optical fibers), and modulated with RF frequencies. In such embodiments, the tunable EM scattering elements **120** may be actuated by optical fields. For example, the tunable EM scattering elements **120** may include photo-diodes, photo-transistors, other semiconductor-based elements affected by the photo-doping effect, or combinations thereof. By way of non-limiting example, the tunable EM scattering elements **120** may include gain media that can be optically pumped by the control lines in a time-dependent fashion. The tunable EM scattering elements **120** may include photo-sensitive media, which experience reversible transitions depending on the intensity of the optical fields delivered by the control lines **134**.

[0172] In some embodiments, the control fields delivered by the control lines **134** are acoustic (e.g., elastodynamic, ultrasonic, phononic, etc.) vibrations, and the control lines **134** include acoustic waveguides. The tunable EM scattering elements **120** modulated by these fields may include piezoelectric elements, magnetostrictive elements, microelectromechanical (MEM) elements with electric field actuation, other tunable acoustic elements, or combinations thereof.

[0173] FIG. **2** is a simplified flowchart illustrating a method **200** of operating an antenna system (e.g., the antenna system **100** of FIG. **1**). Referring to FIGS. **1** and **2** together, the method **200** includes receiving and propagating **210** an EM signal **102** as an EM reference wave **112**. In some embodiments, receiving and propagating **210** the EM signal **102** as an EM reference wave **112** includes receiving the EM signal **102** through an EM transmission line, and propagat-

ing the EM reference wave **112** on or in a body including tunable EM scattering elements **120**.

[0174] The method **200** also includes operating **220** the tunable EM scattering elements **120** to selectively scatter the EM reference wave **112** as a radiated wave **122**. In some embodiments, operating **220** the tunable EM scattering elements **120** includes applying controls to the tunable scattering elements **120** through control lines **134** that are decoupled from each other. By way of non-limiting example, applying controls through control lines **134** that are decoupled from each other may include applying optical signals through the control lines **134**. Also by way of non-limiting example, applying controls through control lines **134** that are decoupled from each other may include applying acoustic signals through the control lines **134**.

[0175] The method **200** further includes modulating **230** the radiated wave **122** by modulating the tunable EM scattering elements **120** between different operational states to deliver a plurality of different information streams to a plurality of different far-end locations **140**.

[0176] In some embodiments, receiving **210** an EM signal **102** includes receiving a monochromatic sinusoidal signal. Since modulating **230** of the EM radiated wave **122** is performed by the modulating the tunable EM scattering elements **120**, even a monochromatic sinusoidal signal fed to the feeds **110** of the antenna system **100** can be used to create a plurality (e.g., a very large number) of different information streams at the plurality of different far-end locations **140**. In some embodiments, however, some modulation of the EM signals **102** may be used to create some modulation in the radiated wave **122** in addition to the modulation that results from modulating **230** the radiated wave **122** by modulating the tunable EM scattering elements **120**.

[0177] Receivers at the far-end locations **140** may receive the separate information streams, which may each be delivered simultaneously using the same EM frequencies. In this way, a large number of different information streams can be transmitted using a single EM signal **102**, or using a few EM signals **102**, being fed to the feeds **110**. This is in contrast to separately modulated signals being fed for each of the far-end receivers. Also, separate multiplexing systems (e.g., code division multiplexing, frequency division multiplexing, time division multiplexing, space division multiplexing, etc.) for each far-end location **140** may be avoided.

[0178] FIG. **3** is a simplified block diagram of a controller **132**A that may be used as the controller **132** of the antenna system **100** of FIG. **1**. The controller **132**A includes at least one processor **370** (sometimes referred to herein simply as "processor" **270**) operably coupled to at least one data storage device **380** (sometimes referred to herein simply as "storage" **380**). The storage **380** includes computer-readable instructions stored thereon. The computer-readable instructions are configured to instruct the processor **370** to perform operations that the controller **132**A is configured to perform. By way of non-limiting example, the computer-readable instructions may be configure to instruct the processor **370** to perform at least a portion of the operations of the method **200** of FIG. **2**.

[0179] In some embodiments, the storage **380** includes a volatile data storage device, a non-volatile data storage device, or combinations thereof. By way of non-limiting example, the storage **380** may include a Flash drive, a hard drive, a solid state drive, a memory card and or/card reader,

an optical drive and/or optical disk, a thumb drive, electrically programmable read only memory (EEPROM), other data storage devices, or combinations thereof.

[0180] The processor 370 includes any device capable of executing the computer-readable instructions stored by the storage 380. By way of non-limiting example, the processor 370 may include a central processing unit (CPU), a microcontroller, a programmable logic controller (PLC), other programmable processor, or combinations thereof.

[0181] It should be understood that the controller 132 of FIG. 1 may include other devices instead of, or in addition to, the controller 132A of FIG. 3. By way of non-limiting example, the controller 132 may include a field programmable gate array (FPGA), an application specific integrated circuit (ASIC), a system on chip (SOC), other hardware elements, or combinations thereof that are configured to perform at least a portion of the functions the controller 132 is configured to perform (e.g., the functions of the method 200 of FIG. 2).

[0182] While various aspects and embodiments have been disclosed herein, other aspects and embodiments will be apparent to those skilled in the art. The various aspects and embodiments disclosed herein are for purposes of illustration and are not intended to be limiting, with the true scope and spirit being indicated by the following claims. Furthermore, the disclosure contemplates combinations of any of the disclosed embodiments and examples, except as would be incompatible in practice, as would be understood by those skilled in the art.

What is claimed is:

1. An antenna system, comprising:

one or more feeds configured to receive an electromagnetic (EM) signal and propagate the EM signal as an EM reference wave;

a plurality of tunable EM scattering elements spaced at sub-wavelength distances, the plurality of tunable EM scattering elements configured to operate in at least two different operational states to selectively scatter the EM reference wave as a radiated wave; and

control circuitry comprising a controller operably coupled to the plurality of tunable EM scattering elements and programmed to modulate the radiated wave over time to deliver a plurality of different information streams to a plurality of different far-end locations by modulating the plurality of tunable EM scattering elements between the plurality of different operational states over time.

2. The antenna system of claim 1, wherein the EM signal is a monochromatic continuous wave EM signal.

3-6. (canceled)

7. The antenna system of claim 1, wherein the controller is programmed to control the tunable EM scattering elements through control lines, wherein each of the control lines is isolated and decoupled from each of the others of the control lines.

8. The antenna system of claim 7, further comprising a plurality of high-frequency EM transmission lines operably coupling the controller to the plurality of tunable EM scattering elements, wherein the plurality of high-frequency EM transmission lines is configured to transmit EM waves having a frequency of at least about twice a frequency of the reference wave.

9. The antenna system of claim 8, wherein the plurality of high-frequency EM transmission lines includes a plurality of

optical transmission lines, and the plurality of tunable EM scattering elements includes a plurality of optically tunable EM scattering elements tunable by optical signals transmitted through the plurality of optical transmission lines.

10. The antenna system of claim 9, wherein the plurality of optical transmission lines includes a plurality of optical fibers.

11-14. (canceled)

15. The antenna system of claim 9, wherein the controller is programmed to modulate the plurality of optically tunable EM scattering elements at a frequency of at least about one (1) gigahertz.

16. The antenna system of claim 9, wherein the controller is programmed to modulate the plurality of optically tunable EM scattering elements at a time scale that is longer than a time that it takes for the radiated wave to travel from the plurality of optically tunable EM scattering elements to the plurality of different far-end locations.

17. The antenna system of claim 16, wherein the controller is programmed to modulate the plurality of optically tunable EM scattering elements as a temporal series of modulation patterns, wherein each modulation pattern of the series is determined by solving a time invariant holographic projection manifold function.

18. The antenna system of claim 17, wherein the controller is programmed to solve the time invariant holographic projection manifold functions using a Green's function.

19. The antenna system of claim 9, wherein the controller is programmed to modulate the plurality of optically tunable EM scattering elements at a time scale that is shorter than a time that it takes for the radiated wave to travel from the plurality of optically tunable EM scattering elements to the plurality of different far-end locations.

20. The antenna system of claim 19, wherein the controller is programmed to modulate the plurality of optically tunable EM scattering elements as a series of modulation patterns, wherein at least a portion of the modulation patterns of the series is determined by solving a time variant holographic projection manifold function.

21. The antenna system of claim 20, wherein the controller is programmed to solve the time variant holographic projection manifold function using a retarded Green's function.

22. The antenna system of claim 9, wherein the two or more different operational states comprises more than two operational states.

23. The antenna system of claim 22, wherein the controller is programmed to transition the antenna system between different holograms gradually.

24. The antenna system of claim 23, wherein the controller is programmed to transition between the different holograms by smoothing control signals delivered to the plurality of optically tunable EM scattering elements with smoothed Heaviside functions.

25. The antenna system of claim 23, wherein the controller is programmed to transition between the different holograms by smoothing control signals delivered to the plurality of optically tunable EM scattering elements with piecewise-trigonometric functions.

26. (canceled)

27. The antenna system of claim 9, wherein the controller is programmed to modulate the radiated wave over time to deliver a plurality of different frequency modulated information streams to the plurality of different far-end locations.

28-39. (canceled)

40. The antenna system of claim **7**, further comprising a plurality of acoustic transmission lines operably coupling the controller to the plurality of tunable EM scattering elements, and wherein the plurality of tunable EM scattering elements includes a plurality of acoustically tunable EM scattering elements tunable by acoustic signals transmitted through the plurality of acoustic transmission lines.

41-68. (canceled)

69. A method of operating an antenna system, the method comprising:

receiving and propagating an electromagnetic (EM) signal as an EM reference wave;

operating a plurality of tunable EM scattering elements spaced at sub-wavelength distances in at least two different operational states to selectively scatter the EM reference wave as a radiated wave; and

modulating the radiated wave over time to deliver a plurality of different information streams to a plurality of different far-end locations by modulating the plurality of tunable EM scattering elements between the plurality of different operational states over time.

70. The method of claim **69**, wherein receiving and propagating an EM signal comprises receiving and propagating a monochromatic continuous wave EM signal.

71. The method of claim **69**, wherein receiving and propagating an EM signal comprises receiving and propagating a modulated EM signal.

72-74. (canceled)

75. The method of claim **69**, wherein modulating the plurality of tunable EM scattering elements comprises controlling the tunable EM scattering elements through control lines, each of the control lines isolated and decoupled from each of the other control lines.

76. The method of claim **75**, wherein controlling the tunable EM scattering elements through the control lines comprises controlling the tunable EM scattering elements using a plurality of high-frequency EM transmission lines, and using the plurality of high-frequency EM transmission lines to transmit EM waves having a frequency of at least about twice a frequency of the reference wave.

77. The method of claim **76**, wherein controlling the tunable EM scattering elements using a plurality of high-frequency EM transmission lines includes controlling the tunable EM scattering elements using a plurality of optical transmission lines, and wherein the plurality of tunable EM scattering elements includes a plurality of optically tunable EM scattering elements tunable by optical signals transmitted through the plurality of optical transmission lines.

78-107. (canceled)

108. The method of claim **75**, wherein controlling the tunable EM scattering elements with control lines includes controlling the tunable EM scattering elements using a plurality of acoustic transmission lines, and wherein the plurality of tunable EM scattering elements includes a plurality of acoustically tunable EM scattering elements tunable by acoustic signals transmitted through the plurality of acoustic transmission lines.

109-111. (canceled)

112. The method of claim **108**, wherein controlling the plurality of acoustically tunable EM scattering elements comprises modulating the plurality of acoustically tunable EM scattering elements at a frequency of at least about one (1) gigahertz.

113. The method of claim **108**, wherein controlling the plurality of acoustically tunable EM scattering elements comprises modulating the plurality of acoustically tunable EM scattering elements at a time scale that is longer than a time that it takes for the radiated wave to travel from the plurality of acoustically tunable EM scattering elements to the plurality of different far-end locations.

114. The method of claim **113**, wherein modulating the plurality of acoustically tunable EM scattering elements comprises modulating the plurality of acoustically tunable EM scattering elements as a temporal series of modulation patterns, wherein each modulation pattern of the series is determined by solving a time invariant holographic projection manifold function.

115. The method of claim **114**, wherein solving a time invariant holographic projection manifold function comprises solving the time invariant holographic projection manifold functions using a Green's function.

116. The method of claim **108**, wherein controlling the plurality of acoustically tunable EM scattering elements comprises modulating the plurality of acoustically tunable EM scattering elements at a time scale that is shorter than a time that it takes for the radiated wave to travel from the plurality of acoustically tunable EM scattering elements to the plurality of different far-end locations.

117. The method of claim **116**, wherein modulating the plurality of acoustically tunable EM scattering elements comprises modulating the plurality of acoustically tunable EM scattering elements as a series of modulation patterns, wherein at least a portion of the modulation patterns of the series is determined by solving a time variant holographic projection manifold function.

118. The method of claim **117**, wherein modulating the plurality of acoustically tunable EM scattering elements as a series of modulation patterns comprises solving the time variant holographic projection manifold function using a retarded Green's function.

119. The method of claim **117**, wherein operating a plurality of tunable EM scattering elements in at least two different operational states comprises operating the plurality of tunable EM scattering elements in more than two operational states.

120. The method of claim **119**, further comprising transitioning the antenna system between different holograms gradually.

121. The method of claim **120**, wherein transitioning the antenna system between different holograms gradually comprises transitioning between the different holograms by smoothing control signals delivered to the plurality of acoustically tunable EM scattering elements with smoothed Heaviside functions.

122. The method of claim **120**, wherein transitioning the antenna system between different holograms gradually comprises transitioning between the different holograms by smoothing control signals delivered to the plurality of acoustically tunable EM scattering elements with piecewise-trigonometric functions.

123. The method of claim **120**, wherein transitioning the antenna system between different holograms gradually comprises transitioning between the different holograms by smoothing control signals delivered to the plurality of acoustically tunable EM scattering elements with spline polynomial functions.

124. The method of claim **108**, wherein controlling the acoustically tunable EM scattering elements comprises modulating the radiated wave over time to deliver a plurality of different frequency modulated information streams to the plurality of different far-end locations.

125-131. (canceled)

132. The method of claim **108**, wherein delivering a plurality of different information streams to a plurality of different far-end locations comprises delivering the plurality of different information streams to at least some of far-end locations coinciding with EM receivers.

133-136. (canceled)
