Note: Within nine months of the publication of the mention of the grant of the European patent in the European Patent Bulletin, any person may give notice to the European Patent Office of opposition to that patent, in accordance with the Implementing Regulations. Notice of opposition shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).

Description

TECHNICAL FIELD

[0001] The present invention relates to the field of information processing technologies, and more specifically, to an information processing method, apparatus, and device.

BACKGROUND

[0002] In recent years, intelligent devices have been increasingly and widely deployed and applied with the development of science and technologies. To satisfy increasing user requirements on richer functions and more diversified forms of the intelligent devices, input manners of the intelligence devices become more intelligent and richer.

[0003] In the prior art, to make it convenient for a user to interact with an intelligent device, a gesture control arm ring is developed. When in use, the gesture control arm ring needs to be worn around a wrist of the user, and implements human-computer interaction by detecting a bioelectricity change that is generated by arm or wrist muscles when the user is in motion, and in combination with monitoring of an arm physical action. The gesture control arm ring may trigger an operation by using a specific action. For example, an action that the user makes a fist and then shakes the wrist up and down for three times may be set as a corresponding action for enabling a device.

[0004] However, there are many operations that can be performed on the intelligent device. If the user wants to operate the intelligent device by using the gesture control arm ring in the prior art, the user needs to remember many correspondences between gesture motions and operations, which makes it extremely inconvenient for the user to use the intelligent device.

[0005] US2011133934 (A1) discloses using the human body as an input mechanism to a computing device. A sensor set is coupled to part of a human body. The sensor set detects mechanical (e.g., bio-acoustic) energy transmitted through the body as a result of an action/Performed by the body, such as a user finger tap or flick. The sensor output data (e.g., signals) are processed to determine what action was taken. For example, the gesture may be a finger tap, and the output data may indicate which finger was tapped, what surface the finger was tapped on, or where on the body the finger was tapped.

[0006] US7109970 (B1) discloses an apparatus for remotely operating a computer using a combination of voice commands and finger movements. The apparatus includes a microphone and a plurality of control elements in the form of touch-sensitive touchpads and/or motion-sensitive elements that are used to operate the computer and to move an on-screen cursor. At least one touchpad is used to selectively switch between a command-mode

of operation in which the computer interprets spoken words as commands for operating the computer and any software applications being used, and a text-mode of operation in which the computer interprets spoken words literally as text to be inserted into a software application.

[0007] US2008129694 (A1) provides a method and apparatus used to create computer input. The apparatus includes a wearable glove constituted to sense the motions of the wearer's wrist and finger joints. Information regarding the motion of the wearer's joints is transmitted to a computer program which uses the method of the invention to interpret said motion as computer input such as might otherwise be provided by a computer keyboard and/or a computer mouse input device.

[0008] WO2006028313 (A1) discloses a keypad glove apparatus which includes a keypad glove apparatus comprising a key pad glove that includes key switches on locations of each of the phalanges of fingers of one hand of the user, wherein one or more of the predetermined symbols are allocated on each of the key switches, a plurality of touching sensors mounted on a respective fingers of the other hand of the user, each of which is operated a corresponding row of key switches, wherein a row indicates a row of phalanges spanning across multiple fingers, and a microcontroller unit that outputs recognition signals of a corresponding key switch when a key switch contacted by the predetermined touching sensor is included in a predesigned key switch row designed to be matched with the corresponding touching sensor.

[0009] US2013082922 (A1) is directed to a system for human-computer interface, comprising an input device configured to provide two or more dimensions of operational input to a processor based at least in part upon a rubbing contact pattern between two or more digits of the same human hand that is interpreted by the input device. The input device may be configured to provide two orthogonal dimensions of operational input pertinent to a three-dimensional virtual environment presented, at least in part, by the processor. The input device may be configured to detect the rubbing between a specific digit in a pen-like function against one or more other digits. The input device further may be configured to detect the rubbing between the specific digit in a pen-like function and one or more other digits in a receiving panel function.

SUMMARY

[0010] The invention is defined by the appended independent claims.

[0011] Further embodiments are defined by the dependent claims.

[0012] According to a first aspect, the present application discloses an information processing method, including:

acquiring mode-enabling gesture information of a user;
enabling an input mode corresponding to the mode-

enabling gesture information, where the input mode includes a keyboard input mode and a mouse input mode;

acquiring gesture information of the user in the input mode, where the gesture information includes tap-gesture information and/or slide-gesture information; and

generating, according to a preset correspondence between gesture information and an operation instruction, an operation instruction corresponding to the gesture information.

[0013] In a first possible implementation manner of the first aspect, when the input mode is the keyboard input mode, there is a one-to-one correspondence between 12 finger joints or finger phalanxes of an index finger, a middle finger, a ring finger, and a little finger of a user and 12 keys of a 12-key keypad;

the acquiring gesture information of the user in the input mode includes: acquiring, in the keyboard input mode, tap-gesture information of tapping any finger joint or finger phalanx of the index finger, the middle finger, the ring finger, and the little finger by the user; and

correspondingly, the generating, according to a preset correspondence between gesture information and an operation instruction, an operation instruction corresponding to the gesture information includes: generating, according to a preset correspondence between tap-gesture information and an operation instruction, an operation instruction corresponding to the tap-gesture information.

[0014] In a second possible implementation manner of the first aspect, when the input mode is the mouse input mode, the acquiring gesture information of the user in the input mode includes:

acquiring, in the mouse input mode, slide-gesture information of sliding on an index finger, a middle finger, a ring finger, and a little finger of the user and/or tap-gesture information of tapping a finger joint or a finger phalanx; and

correspondingly, the generating, according to a preset correspondence between gesture information and an operation instruction, an operation instruction corresponding to the gesture information includes:

generating, according to a preset correspondence between slide-gesture information and/or tap-gesture information and an operation instruction, an operation instruction corresponding to the slide-gesture information and/or the tap-gesture information, where the slide-gesture information is corresponding to movement track information of a mouse pointer, and the tap-gesture information is corre-

sponding to trigger information of a left or right mouse button.

[0015] In a third possible implementation manner of the first aspect, the enabling an input mode corresponding to the mode-enabling gesture information includes:

enabling the keyboard input mode when the mode-enabling gesture information is corresponding to a gesture of extending an index finger, a middle finger, a ring finger, and a little finger of the user; and enabling the mouse input mode when the mode-enabling gesture information is corresponding to a gesture of curling the index finger, the middle finger, the ring finger, and the little finger toward the palm of the user, where the mode-enabling gesture information or the gesture information is detected by a sensor disposed on a wrist or a palm of the user.

[0016] In a fourth possible implementation manner of the first aspect, the acquiring mode-enabling gesture information of a user or the acquiring gesture information of the user in the input mode includes:

acquiring a pressure value of each part of the wrist or the palm when the sensor disposed on the wrist or the palm of the user detects an input mode-enabling gesture motion or a gesture motion of the user; determining a displacement value of the sensor on the wrist or the palm of the user according to the pressure value; and determining, according to the displacement value, mode-enabling gesture information input by the user.

[0017] In any one of the foregoing implementation manners of the first aspect, after the generating, according to a preset correspondence between gesture information and an operation instruction, an operation instruction corresponding to the gesture information, the method further includes:

sending the operation instruction to a terminal so that the terminal responds to the operation instruction.

[0018] According to a second aspect, an information processing method is disclosed, including:

confirming that a keyboard input mode is entered, where in the keyboard input mode, there is a one-to-one correspondence between 12 finger joints or finger phalanxes of an index finger, a middle finger, a ring finger, and a little finger of a user and 12 keys of a 12-key keypad;

acquiring tap-gesture information of tapping any finger joint or finger phalanx of the index finger, the middle finger, the ring finger, and the little finger by the user; and generating, according to a preset correspondence

between tap-gesture information and an operation instruction, an operation instruction corresponding to the tap-gesture information.

[0019] According to a third aspect, an information processing method is disclosed, including:

confirming that a mouse input mode is entered; acquiring slide-gesture information of a user on an index finger, a middle finger, a ring finger, and a little finger and/or tap-gesture information of tapping a finger joint or a finger phalanx of the index finger, the middle finger, the ring finger, and the little finger by the user; and

generating, according to a preset correspondence between slide-gesture information and/or tap-gesture information and an operation instruction, an operation instruction corresponding to the slide-gesture information and/or the tap-gesture information, where

the slide-gesture information is corresponding to movement track information of a mouse pointer, and the tap-gesture information is corresponding to trigger information of a left or right mouse button.

[0020] According to a fourth aspect, an information processing apparatus is disclosed, including:

a first acquiring module, configured to acquire mode-enabling gesture information of a user; a mode enabling module, configured to enable an input mode corresponding to the mode-enabling gesture information, where the input mode includes a keyboard input mode and a mouse input mode; a second acquiring module, configured to acquire gesture information of the user in the input mode, where the gesture information includes tap-gesture information and/or slide-gesture information; and an instruction generation module, configured to generate, according to a preset correspondence between gesture information and an operation instruction, an operation instruction corresponding to the gesture information.

[0021] In a first possible implementation manner of the fourth aspect, when the input mode is the keyboard input mode, there is a one-to-one correspondence between 12 finger joints or finger phalanges of an index finger, a middle finger, a ring finger, and a little finger of a user and 12 keys of a 12-key keypad; the second acquiring module is specifically configured to: acquire, in the keyboard input mode, tap-gesture information of tapping any finger joint or finger phalanx of the index finger, the middle finger, the ring finger, and the little finger by the user.

[0022] In a second possible implementation manner of the fourth aspect, when the input mode is the mouse input mode, the second acquiring module is specifically

configured to:

acquire, in the mouse input mode, slide-gesture information of sliding on an index finger, a middle finger, a ring finger, and a little finger of the user and/or tap-gesture information of tapping a finger joint or a finger phalanx, where

the slide-gesture information is corresponding to movement track information of a mouse pointer, and the tap-gesture information is corresponding to trigger information of a left or right mouse button.

[0023] In a third possible implementation manner of the fourth aspect, the mode enabling module includes:

a first mode enabling module, configured to enable the keyboard input mode when the mode-enabling gesture information is corresponding to a gesture of extending an index finger, a middle finger, a ring finger, and a little finger of the user; and

a second mode enabling module, configured to enable the mouse input mode when the mode-enabling gesture information is corresponding to a gesture of curling the index finger, the middle finger, the ring finger, and the little finger toward the palm of the user.

[0024] In a fourth possible implementation manner of the fourth aspect, the mode-enabling gesture information or the gesture information are detected by a sensor disposed on a wrist or a palm of the user.

[0025] In a fifth possible implementation manner of the fourth aspect, the first acquiring module or the second acquiring module includes:

an acquiring submodule, configured to acquire a pressure value of each part of the wrist or the palm when the sensor disposed on the wrist or the palm of the user detects an input mode-enabling gesture motion or a gesture motion of the user;

a calculation module, configured to determine a displacement value of the sensor on the wrist or the palm of the user according to the pressure value; and a gesture determining module, configured to determine, according to the displacement value, mode-enabling gesture information input by the user.

[0026] In any one of the foregoing possible implementation manners of the fourth aspect, the apparatus further includes:

an instruction transfer module, configured to send the operation instruction to a terminal so that the terminal responds to the operation instruction.

[0027] According to a fifth aspect, an information processing apparatus is disclosed, including:

a first input enabling module, configured to confirm that a system enters a keyboard input mode, where in the keyboard input mode, there is a one-to-one

correspondence between 12 finger joints or finger phalanxes of an index finger, a middle finger, a ring finger, and a little finger of a user and 12 keys of a 12-key keypad;

a first gesture acquiring module, configured to acquire tap-gesture information of tapping any finger joint or finger phalanx of the index finger, the middle finger, the ring finger, and the little finger by the user; and

a first instruction generation module, configured to generate, according to a preset correspondence between tap-gesture information and an operation instruction, an operation instruction corresponding to the tap-gesture information.

[0028] According to a sixth aspect, an information processing apparatus is disclosed, including:

a second input enabling module, configured to confirm that a system enters a mouse input mode;

a second gesture acquiring module, configured to acquire slide-gesture information of a user on an index finger, a middle finger, a ring finger, and a little finger and/or tap-gesture information of tapping a finger joint or a finger phalanx of the index finger, the middle finger, the ring finger, and the little finger by the user; and

a second instruction generation module, configured to generate, according to a preset correspondence between slide-gesture information and/or tap-gesture information and an operation instruction, an operation instruction corresponding to the slide-gesture information and/or the tap-gesture information.

[0029] According to a seventh aspect, an information processing device is disclosed, where the information processing device includes any one of the foregoing information processing apparatuses.

[0030] According to an eighth aspect, an intelligent terminal is disclosed, where the intelligent terminal includes any one of the foregoing information processing apparatuses.

[0031] It may be learned from the foregoing technical solution that, compared with the prior art, embodiments of the present invention disclose an information processing method, apparatus, and device. In the information processing method, mode-enabling gesture information input by a user is first acquired; then a corresponding input mode is entered according to the mode-enabling gesture information input by the user, and gesture information of the user is identified in a determined input mode; further, a user intention is identified according to a preset correspondence between gesture information and an operation instruction. The foregoing input mode includes a keyboard input mode and a mouse input mode. In this way, the user can implement convenient control of a terminal in a familiar input mode environment by using only a customary input operation manner, for ex-

ample, a tap operation and a touch-slide operation. In this method, the apparatus and the device do not require the user to memorize multiple correspondences between specific gesture motions and specific operations. Only by implanting beforehand a correspondence between a customary basic input operation of a user and a standard keyboard and/or mouse operation event into an execution body of the information processing method, a purpose of controlling the terminal by the user in a customary operation manner can be achieved.

BRIEF DESCRIPTION OF DRAWINGS

[0032] To describe the technical solutions in the embodiments of the present invention or in the prior art more clearly, the following briefly introduces the accompanying drawings required for describing the embodiments or the prior art. Apparently, the accompanying drawings in the following description show merely the embodiments of the present invention, and a person of ordinary skill in the art may still derive other drawings from these accompanying drawings without creative efforts.

FIG. 1 is a flowchart of an information processing method according to an embodiment of the present invention;

FIG. 2 is a schematic diagram of a correspondence between 12 keys of a 12-key keypad according to an embodiment of the present invention;

FIG. 3 is a flowchart of acquiring mode-enabling gesture information or gesture information of a user according to an embodiment of the present invention;

FIG. 4 is a schematic diagram of a location of a sensor disposed in a wristband according to an embodiment of the present invention;

FIG. 5 is a flowchart of another information processing method according to an embodiment of the present invention;

FIG. 6 is a flowchart of a third information processing method according to an embodiment of the present invention;

FIG. 7 is a flowchart of a fourth information processing method according to an embodiment of the present invention;

FIG. 8 is a schematic structural diagram of an information processing apparatus according to an embodiment of the present invention;

FIG. 9 is a schematic structural diagram of a first acquiring module according to an embodiment of the present invention;

FIG. 10 is a schematic structural diagram of another information processing apparatus according to an embodiment of the present invention;

FIG. 11 is a schematic structural diagram of a third information processing apparatus according to an embodiment of the present invention;

FIG. 12 is a schematic structural diagram of a fourth information processing apparatus according to an

embodiment of the present invention;
 FIG. 13 is a schematic diagram of communication between an information processing device and a terminal according to an embodiment of the present invention;
 FIG. 14 is a schematic structural diagram of an information processing device according to an embodiment of the present invention; and
 FIG. 15 is a schematic structural diagram of another information processing device according to an embodiment of the present invention.

DESCRIPTION OF EMBODIMENTS

[0033] The following clearly and completely describes the technical solutions in the embodiments of the present invention with reference to the accompanying drawings in the embodiments of the present invention. Apparently, the described embodiments are merely some but not all of the embodiments of the present invention. All other embodiments obtained by a person of ordinary skill in the art based on the embodiments of the present invention without creative efforts shall fall within the protection scope of the present invention.

[0034] FIG. 1 is a flowchart of an information processing method according to an embodiment of the present invention. As shown in FIG. 1, the method may include:
 Step 101: Acquire mode-enabling gesture information of a user.

[0035] In this embodiment of the present invention, there may be multiple input modes for the user, and each input mode is corresponding to one mode-enabling gesture. In this way, an execution body of the information processing method disclosed in this embodiment of the present invention may automatically identify, according to mode-enabling gesture information input by the user, an input mode currently wanted by the user, which facilitates use for the user.

[0036] Step 102: Enable an input mode corresponding to the mode-enabling gesture information.

[0037] The input mode may include a keyboard input mode and a mouse input mode. The keyboard input mode described herein indicates that in this mode, the user may directly trigger a character on a known keyboard by tapping a part of a finger, where the character may be a digit, an English letter, or a symbol with a fixed function, for example, a "#" key. Certainly, it is required to preconfigure a correspondence between gesture information of tapping or triggering a part of a finger by the user and each key of the known keyboard. The foregoing mouse input mode indicates that in this mode, the user may perform a corresponding operation on a finger or a palm like operating a mouse. In this case, an operation may include a slide operation and a tap operation. For example, a thumb of the user slides leftwards on a finger or the palm, which is corresponding to a leftward slide of a mouse pointer; the user taps a part of a finger or the palm, which is corresponding to a click on a left mouse button. Cer-

tainly, in this case, it is also required to preconfigure a correspondence between gesture information of a user and a standard mouse operation event.

[0038] Step 103: Acquire gesture information of the user in the input mode.

[0039] The gesture information may include tap-gesture information and/or slide-gesture information.

[0040] It should be noted that, for same gesture information, different processing and response results may be obtained in different input modes, and a piece of gesture information may be processed and responded to in one input mode, but may not be processed and responded to in another input mode. It has been described in the foregoing that, in the keyboard input mode, a character that the user wants to trigger may be determined by acquiring gesture information of tapping a part of the palm by the user. In this mode, if the user inputs slide-gesture information, a system does not process and respond to the slide-gesture information. However, if the user inputs slide-gesture information in the mouse input mode, the slide-gesture information is processed and responded to, because the slide-gesture information may be corresponding to a mouse pointer movement operation. In addition, such a correspondence accords with a user habit of performing an input operation on a computer interface by using a mouse or performing an input operation directly on a touchscreen interface in the prior art. For example, the user may experience corresponding up, down, left, and right page-turning operations on the touchscreen by moving the thumb up, down, left, and right on the palm.

[0041] Step 104: Generate, according to a preset correspondence between gesture information and an operation instruction, an operation instruction corresponding to the gesture information.

[0042] A correspondence between gesture information and an operation instruction is implanted beforehand into a system program, which can be implemented by using the prior art. However, in this embodiment of the present invention, multiple input modes are introduced, and there is a separate correspondence between gesture information and an operation instruction in each input mode, because different processing and response results may be obtained in different input modes for same gesture information, which has been described above.

[0043] Further, the operation instruction generated according to the gesture information of the user may be transferred to a terminal, so that the terminal performs a response operation according to the operation instruction.

[0044] In the information processing method in this embodiment, mode-enabling gesture information input by a user is first acquired; then a corresponding input mode is entered according to the mode-enabling gesture information input by the user, and gesture information of the user is identified in a determined input mode; further, a user intention is identified according to a preset correspondence between gesture information and an opera-

tion instruction. The foregoing input mode includes a keyboard input mode and a mouse input mode. In this way, the user can implement convenient control of a terminal in a familiar input mode environment by using only a customary input operation manner, for example, a tap operation and a touch-slide operation. In this method, the user does not need to memorize multiple correspondences between specific gesture motions and specific operations. Only by implanting beforehand a correspondence between a customary basic input operation of a user and a standard keyboard and mouse operation event into an execution body of the information processing method, a purpose of conveniently performing an input operation and controlling the terminal by the user in a customary operation manner can be achieved.

[0045] In the foregoing embodiment, when mode-enabling gesture information acquired by a system is a mode-enabling gesture corresponding to the keyboard input mode, the system enables the keyboard input mode. In this mode, there may be a one-to-one correspondence between 12 finger joints or finger phalanxes of an index finger, a middle finger, a ring finger, and a little finger of a user and 12 keys of a 12-key keypad. It is known to all that the 12-key keypad includes 1, 2 (abc), 3 (def), 4 (ghi), 5 (jkl), 6 (mno), 7 (pqrs), 8 (tuv), 9 (wyxz), *, 0, and # keys. In addition, in a hand structure, each of an index finger, a middle finger, a ring finger, and a little finger includes three finger joints and three finger phalanxes, and the index finger, the middle finger, the ring finger, and the little finger altogether include 12 finger joints and 12 finger phalanxes. In addition, a 4*3 array of the 12 keys of the 12-key keypad is the same as a 4*3 array of the 12 finger joints or finger phalanxes of the index finger, the middle finger, the ring finger, and the little finger in the hand structure. Reference may be made to FIG. 2, and FIG. 2 is a schematic diagram of a correspondence between 12 keys of a 12-key keypad according to an embodiment of the present invention. A first finger phalanx of the index finger may be corresponding to the "1" key, a second finger phalanx of the index finger may be corresponding to the "2" key, ..., and a third finger phalanx of the little finger may be corresponding to the "#" key.

[0046] Certainly, a correspondence between keys of a 12-key keypad and 12 finger joints or finger phalanxes is not fixedly limited to the foregoing manner. It may also be set that three finger joints of the little finger are respectively corresponding to the "1" key, the "2" key, and the "3" key, and three finger joints of the index finger are respectively corresponding to the "*" key, the "0" key, and the "#" key. A specific correspondence may be set according to user preference and habits.

[0047] In this way, in the foregoing embodiment, step 103 of acquiring gesture information of the user in the input mode may include: acquiring, in the keyboard input mode, tap-gesture information of tapping any finger joint or finger phalanx of the index finger, the middle finger, the ring finger, and the little finger by the user.

[0048] Correspondingly, step 104 of generating, according to a preset correspondence between gesture information and an operation instruction, an operation instruction corresponding to the gesture information may include: generating, according to a preset correspondence between tap-gesture information and an operation instruction, an operation instruction corresponding to the tap-gesture information.

[0049] In this embodiment, keys of a 12-key keypad are respectively one-to-one corresponding to 12 finger joints or finger phalanxes, and such a correspondence is preconfigured in a system.

[0050] Because basically all users are extremely familiar with a usage method of the 12-key keypad, and can also accurately sense locations of several finger joints or finger phalanxes, the users can conveniently and quickly implement information input without needing to memorize a correspondence between each key of a 12-key keypad and a fixed gesture motion.

[0051] In a first embodiment, when mode-enabling gesture information acquired by a system is a mode-enabling gesture corresponding to the mouse input mode, the system enables the mouse input mode. In this mode, step 103 of acquiring gesture information of the user in the input mode may include: acquiring, in the mouse input mode, slide-gesture information of sliding on an index finger, a middle finger, a ring finger, and a little finger of the user and/or tap-gesture information of tapping a finger joint or a finger phalanx.

[0052] Correspondingly, step 104 of generating, according to a preset correspondence between gesture information and an operation instruction, an operation instruction corresponding to the gesture information may include: generating, according to a preset correspondence between slide-gesture information and/or tap-gesture information and an operation instruction, an operation instruction corresponding to the slide-gesture information and/or the tap-gesture information.

[0053] In the mouse input mode, it may be preconfigured that the slide-gesture information of the user is corresponding to movement track information of a mouse pointer, and the tap-gesture information of the user is corresponding to trigger information of a left or right mouse button.

[0054] Specifically, the user may curl four fingers except the thumb to form a "panel". The thumb may move on the "panel" to simulate a mouse movement on a display screen. Certainly, a correspondence between gesture information of a user and a standard mouse operation event needs to be preconfigured. In consideration of a user habit of using a PAD and performing an operation by using a mouse, leftward slide-gesture information of the user may be directly corresponding to a leftward mouse pointer movement operation, upward slide-gesture information of the user may be directly corresponding to an upward mouse pointer movement operation, and so on. In this way, the thumb of user is equivalent to the mouse on the "panel" formed by the four fingers, and

the "panel" is equivalent to the display screen. Gesture information of the thumb of user on the "panel" may also be corresponding to a user operation event of operating a physical touchscreen, so that the user can experience an operation on the touchscreen by using the "panel" formed by the four fingers.

[0055] In an actual scenario, the mouse includes a left button and a right button. To facilitate use for the user, in this embodiment, in the mouse input mode, a gesture motion of tapping any fingertip of the index finger, the middle finger, the ring finger, and the little finger by the user may be defined as a left mouse button trigger operation; a gesture motion of tapping any finger root of the index finger, the middle finger, the ring finger, and the little finger by the user may be defined as a right mouse button trigger operation. Alternatively, a gesture motion of tapping the fingertip of the index finger by the user may be defined as a left mouse button trigger operation, a gesture motion of tapping the fingertip of the middle finger by the user may be defined as a right mouse button trigger operation, or the like, which is not limited herein.

[0056] In this embodiment, several pieces of fixed gesture information of a user are corresponding to several basic operations of mouse operations, so that the user directly implements an input operation by performing a gesture motion on a palm in a familiar mouse operation manner or touchscreen operation manner, which is convenient and efficient, and the user does not need to memorize multiple correspondences between gesture motions and operations.

[0057] It may be understood that, in the foregoing embodiment, mode-enabling gestures corresponding to different input modes are not fixedly limited. To facilitate use for a user, in this embodiment, step 102 that is in the first embodiment and is of enabling an input mode corresponding to the mode-enabling gesture information is specifically: enabling the keyboard input mode when the mode-enabling gesture information is corresponding to a gesture of extending an index finger, a middle finger, a ring finger, and a little finger of the user; and enabling the mouse input mode when the mode-enabling gesture information is corresponding to a gesture of curling the index finger, the middle finger, the ring finger, and the little finger toward the palm of the user.

[0058] Because the user may unconsciously separate several fingers when tapping different finger joints or finger phalanxes of the index finger, the middle finger, the ring finger, and the little finger, the gesture of extending the index finger, the middle finger, the ring finger, and the little finger of the user is corresponding to the keyboard input mode; the gesture of curling the index finger, the middle finger, the ring finger, and the little finger toward the palm of the user is corresponding to the mouse input mode, and a "panel" formed by the four curled fingers may be used to simulate a display screen, which is relatively close to a user operation habit. Certainly, mode-enabling gestures of the keyboard input mode and the mouse input mode are not fixedly limited.

[0059] In the foregoing embodiment, the mode-enabling gesture information or the gesture information may be detected by a sensor disposed on a wrist or a palm of the user.

[0060] It should be noted that, the sensor disposed on the wrist or the palm of the user can detect a mode-enabling gesture motion or a gesture motion of a hand with the sensor.

[0061] FIG. 3 is a flowchart of acquiring mode-enabling gesture information or gesture information of a user according to an embodiment of the present invention. As shown in FIG. 3, a specific process of the acquiring mode-enabling gesture information of a user and the acquiring gesture information of the user may include:

15 Step 301: Acquire a pressure value of each part of a wrist or a palm when a sensor disposed on the wrist or the palm of a user detects an input mode-enabling gesture motion or a gesture motion of the user.

[0062] The sensor disposed on the wrist of the user 20 may be disposed in a wristband, and the sensor disposed on the palm of the user may be disposed in a glove or a mitten. If the sensor is disposed on the wrist of the user, gesture motions of the user may be determined according to different pressure that is caused by a muscle 25 change and a motion change of each part of the wrist when the user makes different gestures. If the sensor is disposed on the palm of the user, gesture motions of the user may also be determined according to different pressure caused by a muscle change and a motion change 30 of each part of the palm. If the sensor is disposed on a finger of the user, the sensor on the finger may directly detect touch information of a thumb of the user, to further determine gesture information of the user. It should be noted that, regardless of a location of the sensor disposed 35 on the user hand, the sensor not only may be used to detect related sensing information of a mode-enabling gesture, but also may be used to detect sensing information of a related gesture when the user performs a slide operation or a tap operation on the palm or the finger 40 after a system enters a keyboard input mode or a mouse input mode.

[0063] Step 302: Determine a displacement value of the sensor on the wrist or the palm of the user according to the pressure value.

[0064] Generally, a larger pressure change indicates a larger displacement value. After the user wears an apparatus with a sensor, in a case in which the user does not make any gesture motion, contact pressure between the apparatus with a sensor and user hand skin has a basically stable initial value. However, when the user makes a gesture motion, a pressure value of a part of the hand may become larger, or may become smaller. Therefore, displacement of hand muscles also has different vector directions. Larger pressure indicates a larger displacement value of the sensor shifting from an original location. In this embodiment, there may be multiple sensors disposed on the wrist or the palm of the user, and the sensors may be disposed on different parts ac-

cording to a requirement, so as to improve accuracy of a detection result.

[0065] Step 303: Determine, according to the displacement value, mode-enabling gesture information input by the user.

[0066] FIG. 4 is a schematic diagram of a location of a sensor disposed in a wristband according to an embodiment of the present invention. As shown in FIG. 4, a round of pressure sensors may be disposed in the wristband, where when a user gesture changes, each sensor may obtain, according to a measured pressure variation value, a location offset of the sensor from an initial location of the sensor (that is, a location of the sensor when the user does not make any motion, and a hand is in a natural state). In this way, as long as a muscle group of a user wrist changes because of a finger motion, a gesture motion of the user may be finally determined according to data detected by the sensors. A muscle group closer to a finger changes more obviously.

[0067] Therefore, the sensors in the wristband may be disposed at a location close to the finger.

[0068] In an actual situation, a location at which the user wears the wristband each time may be different. Therefore, data detected by the sensors in the wristband each time also is different, thereby affecting accuracy of a detection result. In this embodiment, to address impact of the foregoing problem on the accuracy of the detection result, the following provides two solutions.

[0069] Solution 1: Build a database as comprehensive as possible to store a correspondence between data detected by a sensor and a gesture motion when the wristband is at different locations.

[0070] Solution 2: Dispose multiple rounds of sensors in the wristband. When using the wristband for the first time, the user may use data detected by a round of sensors located in the middle of the wristband, and complete related calibration work, so as to ensure that the round of sensors located in the middle of the wristband can accurately identify a gesture motion of the user. When the user uses the wristband subsequently, a location of the wristband may be different from a previous location. In this case, each round of sensors in the wristband may directly determine a current location of the wristband according to related displacement data (different locations of the wrist have different diameters, and therefore a cross-section shape formed by a current round of sensors may be obtained by means of calculation according to displacement data detected by the sensors, so as to estimate a location of the wristband on the wrist), and calculate a location difference between a current location of the sensor, and a location of the sensor when the wristband is used for the first time, so as to complete a deviation correction. Alternatively, in a process of using the wristband, a round of sensors closest to the round of sensors that is located in the middle of the wristband when the wristband is used for the first time is automatically found according to current location information corresponding to each round of sensors, and data detected

by the found round of sensors is used.

[0071] A calibration process may be as follows: 1. A user wears a wristband. 2. The wristband establishes communication with a terminal. 3. Enable a calibration mode. 4. Display a calibration interface on a display screen of the terminal. 5. The wristband instructs the terminal to display a "1" key. 6. The user uses the thumb of a hand with the wristband to touch the first finger joint of the index finger, which indicates that the "1" key is pressed, and the touch continues until the terminal completes identification. 7. Current location information of a sensor in the wristband is recorded in the wristband, and the current location information is used as a reference to complete a calibration of the "1" key. For calibration processes of other keys, refer to the foregoing calibration process of the "1" key.

[0072] Certainly, the foregoing method for acquiring the mode-enabling gesture information of the user is also applicable to acquiring of other gesture information of the user.

[0073] In this embodiment, a specific method for acquiring mode-enabling gesture information is given, but is not a unique method for acquiring gesture information of a user. For example, gesture information of a user may further be acquired by using a method for identifying gesture information of a user by using bioelectricity, and by using a method in which a contact sensor is installed at a finger location of a glove. It should be noted that, regardless of a location of a sensor disposed on a user hand, the sensor not only may be used to detect related sensing information of a mode-enabling gesture, but also may be used to detect sensing information of a related gesture when the user performs a slide operation or a tap operation on a palm or a finger after a system enters a keyboard input mode or a mouse input mode.

[0074] FIG. 5 is a flowchart of another information processing method according to an embodiment of the present invention. As shown in FIG. 5, the information processing method may include:

Step 501: Acquire mode-enabling gesture information of a user.

Step 502: Enable an input mode corresponding to the mode-enabling gesture information.

[0075] The input mode includes a keyboard input mode and a mouse input mode.

[0076] Step 503: Acquire gesture information of the user in the input mode.

[0077] The gesture information includes tap-gesture information and/or slide-gesture information.

[0078] Step 504: Generate, according to a preset correspondence between gesture information and an operation instruction, an operation instruction corresponding to the gesture information.

[0079] Step 505: Send the operation instruction to a terminal.

[0080] The operation instruction is sent to the terminal

in step 505, so that the terminal responds to the operation instruction, thereby implementing human-computer interaction.

[0081] In this embodiment, a user can implement convenient control of a terminal by using a customary input operation manner, for example, a tap operation and a touch-slide operation. In this method, the user does not need to memorize multiple correspondences between specific gesture motions and specific operations. Only by implanting beforehand a correspondence between a customary basic input operation of a user and a standard keyboard and mouse operation event into an execution body of the information processing method, a purpose of conveniently performing an input operation and controlling the terminal can be achieved.

[0082] FIG. 6 is a flowchart of a third information processing method according to an embodiment of the present invention. As shown in FIG. 6, the information processing method may include:

Step 601: Confirm that a keyboard input mode is entered.

[0083] In the keyboard input mode, there is a one-to-one correspondence between 12 finger joints or finger phalanxes of an index finger, a middle finger, a ring finger, and a little finger of a user and 12 keys of a 12-key keypad.

[0084] Step 602: Acquire tap-gesture information of tapping any finger joint or finger phalanx of an index finger, a middle finger, a ring finger, and a little finger by a user.

[0085] Step 603: Generate, according to a preset correspondence between tap-gesture information and an operation instruction, an operation instruction corresponding to the tap-gesture information.

[0086] In this embodiment, keys of a 12-key keypad are respectively one-to-one corresponding to 12 finger joints or finger phalanxes, and such a correspondence is preconfigured in a system.

[0087] Because basically all users are extremely familiar with a usage method of the 12-key keypad, and can also accurately sense locations of several finger joints or finger phalanxes, the users can conveniently and quickly implement information input without needing to memorize a correspondence between each key of a 12-key keypad and a fixed gesture motion.

[0088] FIG. 7 is a flowchart of a fourth information processing method according to an embodiment of the present invention. As shown in FIG. 7, the method may include:

Step 701: Confirm that a mouse input mode is entered.

Step 702: Acquire slide-gesture information of a user on an index finger, a middle finger, a ring finger, and a little finger and/or tap-gesture information of tapping a finger joint or a finger phalanx of the index finger, the middle finger, the ring finger, and the little finger by the user.

Step 703: Generate, according to a preset correspondence between slide-gesture information

and/or tap-gesture information and an operation instruction, an operation instruction corresponding to the slide-gesture information and/or the tap-gesture information.

5

[0089] The slide-gesture information is corresponding to movement track information of a mouse pointer, and the tap-gesture information is corresponding to trigger information of a left or right mouse button.

[0090] In this embodiment, several pieces of fixed gesture information of a user are corresponding to several basic operations of mouse operations, so that the user directly implements an input operation by performing a gesture motion on a palm in a familiar mouse operation manner or touchscreen operation manner, which is convenient and efficient, and the user does not need to memorize multiple correspondences between gesture motions and operations.

[0091] The foregoing embodiments disclosed in the present invention describe the methods in detail.

[0092] The methods in the present invention may be implemented by using apparatuses in multiple forms. Therefore, the present invention further discloses an apparatus, which is described in detail in the following by using a specific embodiment.

[0093] FIG. 8 is a schematic structural diagram of an information processing apparatus according to an embodiment of the present invention. As shown in FIG. 8, an information processing apparatus 80 may include: a first acquiring module 801, a mode enabling module 802, a second acquiring module 803, and an instruction generation module 804.

[0094] The first acquiring module 801 is configured to acquire mode-enabling gesture information of a user.

[0095] In this embodiment of the present invention, there may be multiple input modes for the user, and each input mode is corresponding to one mode-enabling gesture.

[0096] The mode enabling module 802 is configured to enable an input mode corresponding to the mode-enabling gesture information.

[0097] The input mode includes a keyboard input mode and a mouse input mode. The keyboard input mode described herein indicates that in this mode, the user may directly trigger a character on a known keyboard by tapping a part of a finger, where the character may be a digit, an English letter, or a symbol with a fixed function. The foregoing mouse input mode indicates that in this mode, the user may perform an operation on a palm like operating a mouse. In this case, an operation may include a slide operation and a tap operation. Certainly, in the foregoing two cases, it is required to preconfigure a correspondence between gesture information of a user and a standard keyboard or mouse operation event.

[0098] The second acquiring module 803 is configured to acquire gesture information of the user in the input mode, where the gesture information includes tap-gesture information

and/or slide-gesture information.

[0099] It should be noted that, for same gesture information, different processing and response results may be obtained in different input modes, and a piece of gesture information may be processed and responded to in an input mode, but may not be processed and responded to in another input mode.

[0100] The instruction generation module 804 is configured to generate, according to a preset correspondence between gesture information and an operation instruction, an operation instruction corresponding to the gesture information.

[0101] A correspondence between gesture information and an operation instruction is implanted beforehand into a system program, which can be implemented by using the prior art. However, in this embodiment of the present invention, multiple input modes are introduced, and there is a separate correspondence between gesture information and an operation instruction in each input mode, because different processing and response results may be obtained in different input modes for same gesture information, which has been described above.

[0102] In this embodiment, the information processing apparatus can first acquire mode-enabling gesture information input by a user; then enter a corresponding input mode according to the mode-enabling gesture information input by the user, and identify gesture information of the user in a determined input mode; further, identify a user intention according to a preset correspondence between gesture information and an operation instruction. The foregoing input mode includes a keyboard input mode and a mouse input mode. In this way, the user can implement convenient control of a terminal in a familiar input mode environment by using only a customary input operation manner, for example, a tap operation and a touch-slide operation. The apparatus does not require the user to memorize multiple correspondences between specific gesture motions and specific operations. Only by implanting beforehand a correspondence between a customary basic input operation of a user and a standard keyboard and mouse operation event into an execution body of the information processing method, a purpose of conveniently performing an input operation and controlling the terminal by the user in a customary operation manner can be achieved.

[0103] In the foregoing embodiment, when the input mode is the keyboard input mode, there is a one-to-one correspondence between 12 finger joints or finger phalanxes of an index finger, a middle finger, a ring finger, and a little finger of a user and 12 keys of a 12-key keypad; the second acquiring module may be specifically configured to: acquire, in the keyboard input mode, tap-gesture information of tapping any finger joint or finger phalanx of the index finger, the middle finger, the ring finger, and the little finger by the user.

[0104] It may be understood that a 4*3 array of the 12 keys of the 12-key keypad is the same as a 4*3 array of the 12 finger joints or finger phalanxes of the index finger,

the middle finger, the ring finger, and the little finger in a hand structure, and therefore, the 12 keys of the 12-key keypad may be one-to-one corresponding to the 12 finger joints or finger phalanxes. However, in this embodiment, a specific correspondence sequence is not specifically limited, and specifically, may be set according to user preference and habits.

[0105] In this embodiment, keys of a 12-key keypad are respectively one-to-one corresponding to 12 finger joints or finger phalanxes, and such a correspondence is preconfigured in a system.

[0106] Because basically all users are extremely familiar with a usage method of the 12-key keypad, and can also accurately sense locations of several finger joints or finger phalanxes, the users can conveniently and quickly implement information input without needing to memorize a correspondence between each key of a 12-key keypad and a fixed gesture motion.

[0107] In a first embodiment, when the input mode is the mouse input mode, the second acquiring module may be specifically configured to: acquire, in the mouse input mode, slide-gesture information of sliding on an index finger, a middle finger, a ring finger, and a little finger of the user and/or tap-gesture information of tapping a finger joint or a finger phalanx.

[0108] In the mouse input mode, it may be preconfigured that the slide-gesture information of the user is corresponding to movement track information of a mouse pointer, and the tap-gesture information of the user is corresponding to trigger information of a left or right mouse button.

[0109] Specifically, to facilitate use for the user, in this embodiment, in the mouse input mode, a gesture motion of tapping any fingertip of the index finger, the middle finger, the ring finger, and the little finger by the user may be defined as a left mouse button trigger operation; a gesture motion of tapping any finger root of the index finger, the middle finger, the ring finger, and the little finger by the user may be defined as a right mouse button trigger operation.

[0110] In this embodiment, several pieces of fixed gesture information of a user are corresponding to several basic operations of mouse operations, so that the user directly implements an input operation by performing a gesture motion on a palm in a familiar mouse operation manner or touchscreen operation manner, which is convenient and efficient, and the user does not need to memorize multiple correspondences between gesture motions and operations.

[0111] It may be understood that, in the foregoing embodiment, mode-enabling gestures corresponding to different input modes are not fixedly limited. To facilitate use for a user, in this embodiment, the mode enabling module may include a first mode enabling module and a second mode enabling module, where the first mode enabling module may be configured to enable the keyboard input mode when the mode-enabling gesture information is corresponding to a gesture of extending an index fin-

ger, a middle finger, a ring finger, and a little finger of the user; and the second mode enabling module may be configured to enable the mouse input mode when the mode-enabling gesture information is corresponding to a gesture of curling the index finger, the middle finger, the ring finger, and the little finger toward the palm of the user.

[0112] Because the user may unconsciously separate several fingers when tapping different finger joints or finger phalanxes of the index finger, the middle finger, the ring finger, and the little finger, the gesture of extending the index finger, the middle finger, the ring finger, and the little finger of the user is corresponding to the keyboard input mode; the gesture of curling the index finger, the middle finger, the ring finger, and the little finger toward the palm of the user is corresponding to the mouse input mode, and a "panel" formed by the four curled fingers may be used to simulate a display screen, which is relatively close to a user operation habit. Certainly, mode-enabling gestures of the keyboard input mode and the mouse input mode are not fixedly limited.

[0113] In the foregoing embodiment, the first acquiring module 801 may be specifically configured to acquire mode-enabling gesture information that is of the user and is detected by a sensor disposed on a wrist or a palm of the user. Correspondingly, the second acquiring module may be specifically configured to acquire gesture information that is of the user and is detected by the sensor disposed on the wrist or the palm of the user. The sensor disposed on the wrist or the palm of the user can detect gesture motion information of a hand with the sensor.

[0114] FIG. 9 is a schematic structural diagram of a first acquiring module according to an embodiment of the present invention. As shown in FIG. 9, the first acquiring module 801 may specifically include an acquiring submodule 901, a calculation module 902, and a gesture determining module 903.

[0115] The acquiring submodule 901 is configured to acquire a pressure value of each part of the wrist or the palm when the sensor disposed on the wrist or the palm of the user detects an input mode-enabling gesture motion or a gesture motion.

[0116] The sensor disposed on the wrist of the user may be disposed in a wristband, and the sensor disposed on the palm of the user may be disposed in a glove or a mitten. If the sensor is disposed on the wrist of the user, gesture motions of the user may be determined according to different pressure that is caused by a muscle change and a motion change of each part of the wrist when the user makes different gestures. If the sensor is disposed on the palm of the user, gesture motions of the user may also be determined according to different pressure caused by a muscle change and a motion change of each part of the palm. If the sensor is disposed on a finger of the user, the sensor on the finger may directly detect touch information of a thumb of the user, to further determine gesture information of the user.

[0117] The calculation module 902 is configured to determine a displacement value of the sensor on the wrist

or the palm of the user according to the pressure value.

[0118] Generally, a larger pressure change indicates a larger displacement value. There are two cases in which pressure becomes larger or smaller. Therefore, displacement also has different directions.

[0119] Larger pressure indicates a larger displacement value of the sensor shifting from an original location. In this embodiment, there may be multiple sensors disposed on the wrist or the palm of the user, and the sensors may be disposed on different parts according to a requirement, so as to improve accuracy of a detection result.

[0120] The gesture determining module 903 is configured to determine, according to the displacement value,

[0121] When the sensor is closer to a finger, a muscle group changes more obviously. Therefore, the sensor in the wristband may be disposed at a location close to the finger.

[0122] In this embodiment, a specific method for acquiring mode-enabling gesture information is given, but is not a unique method for acquiring gesture information of a user. For example, gesture information of a user may further be acquired by using a method for identifying gesture information of a user by using bioelectricity, and by using a method in which a contact sensor is installed at a finger location of a glove.

[0123] FIG. 10 is a schematic structural diagram of another information processing apparatus according to an embodiment of the present invention. As shown in FIG. 10, an information processing apparatus 100 may include:

a first acquiring module 801, configured to acquire mode-enabling gesture information of a user;
 a mode enabling module 802, configured to enable an input mode corresponding to the mode-enabling gesture information; where
 the input mode includes a keyboard input mode and a mouse input mode;
 a second acquiring module 803, configured to acquire gesture information of the user in the input mode; where
 the gesture information includes tap-gesture information and/or slide-gesture information;
 an instruction generation module 804, configured to generate, according to a preset correspondence between gesture information and an operation instruction, an operation instruction corresponding to the gesture information; and
 an instruction transfer module 1001, configured to send the operation instruction to a terminal so that the terminal responds to the operation instruction.

[0124] The instruction transfer module 1001 sends the operation instruction to the terminal so that the terminal responds to the operation instruction, thereby implementing human-computer interaction.

[0125] In this embodiment, a user can implement convenient control of a terminal by using a customary input operation manner, for example, a tap operation and a touch-slide operation. In this method, the user does not need to memorize multiple correspondences between specific gesture motions and specific operations. Only by implanting beforehand a correspondence between a customary basic input operation of a user and a standard keyboard and mouse operation event into an execution body of the information processing method, a process of human-computer interaction can be conveniently implemented.

[0126] FIG. 11 is a schematic structural diagram of a third information processing apparatus according to an embodiment of the present invention. As shown in FIG. 11, an information processing apparatus 110 may include:

a first input enabling module 1101, configured to confirm that a system enters a keyboard input mode, where in the keyboard input mode, there is a one-to-one correspondence between 12 finger joints or finger phalanxes of an index finger, a middle finger, a ring finger, and a little finger of a user and 12 keys of a 12-key keypad;
 a first gesture acquiring module 1102, configured to acquire tap-gesture information of tapping any finger joint or finger phalanx of the index finger, the middle finger, the ring finger, and the little finger by the user; and
 a first instruction generation module 1103, configured to generate, according to a preset correspondence between tap-gesture information and an operation instruction, an operation instruction corresponding to the tap-gesture information.

[0127] In this embodiment, keys of a 12-key keypad are respectively one-to-one corresponding to 12 finger joints or finger phalanxes, and such a correspondence is preconfigured in a system.

[0128] Because basically all users are extremely familiar with a usage method of the 12-key keypad, and can also accurately sense locations of several finger joints or finger phalanxes, the users can conveniently and quickly implement information input without needing to memorize a correspondence between each key of a 12-key keypad and a fixed gesture motion.

[0129] FIG. 12 is a schematic structural diagram of a fourth information processing apparatus according to an embodiment of the present invention. As shown in FIG. 12, an information processing apparatus 120 may include:

a second input enabling module 1201, configured to confirm that a system enters a mouse input mode;
 a second gesture acquiring module 1202, configured to acquire slide-gesture information of a user on an index finger, a middle finger, a ring finger, and a little

finger and/or tap-gesture information of tapping a finger joint or a finger phalanx of the index finger, the middle finger, the ring finger, and the little finger by the user; and

5 a second instruction generation module 1203, configured to generate, according to a preset correspondence between slide-gesture information and/or tap-gesture information and an operation instruction, an operation instruction corresponding to the slide-gesture information and/or the tap-gesture information.

[0130] The slide-gesture information may be corresponding to movement track information of a mouse pointer, and the tap-gesture information may be corresponding to trigger information of a left or right mouse button.

[0131] In this embodiment, several pieces of fixed gesture information of a user are corresponding to several basic operations of mouse operations, so that the user directly implements an input operation by performing a gesture motion on a palm in a familiar mouse operation manner or touchscreen operation manner, which is convenient and efficient, and the user does not need to memorize multiple correspondences between gesture motions and operations.

[0132] Further, an embodiment of the present invention further discloses an information processing device, where the information processing device includes any one of the information processing apparatuses disclosed in the foregoing embodiments. Because the information processing device includes any one of the information processing apparatuses disclosed in the foregoing embodiments, the information processing device can also first acquire mode-enabling gesture information input by a user; then enter a corresponding input mode according to the mode-enabling gesture information input by the user, and identify gesture information of the user in a determined input mode; further, identify a user intention 40 according to a preset correspondence between gesture information and an operation instruction. The foregoing input mode includes a keyboard input mode and a mouse input mode. In this way, the user can implement convenient control of a terminal in a familiar input mode environment by using only a customary input operation manner, for example, a tap operation and a touch-slide operation. The device does not require the user to memorize multiple correspondences between specific gesture motions and specific operations. Only by implanting beforehand a correspondence between a customary basic input 45 operation of a user and a standard keyboard and mouse operation event into an execution body of the information processing method, a purpose of controlling the terminal by the user in a customary operation manner can be achieved.

[0133] Preferably, the information processing device may be any apparatus that has a processing function and can be worn on a user hand. The information processing

device may exchange information with a terminal in a wireless communications manner or a Bluetooth manner.

[0134] Specifically, the information processing device may transfer an operation instruction generated according to the gesture information of the user to the terminal, so that the terminal performs a response operation according to the operation instruction. FIG. 13 is a schematic diagram of communication between an information processing device and a terminal according to an embodiment of the present invention.

[0135] Preferably, the information processing device may be an intelligent terminal integrating the foregoing information processing apparatus and a terminal function, for example, a portable intelligent terminal. A smartwatch is used as an example of the portable intelligent terminal.

[0136] Sensors may be disposed in a watchband of the watch, and the sensors in the watchband may determine gesture motions of the user according to different pressure that is caused by a muscle change and a motion change of each part of a wrist when the user makes different gestures. In this way, as long as a muscle group of a user wrist changes because of a finger motion, the gesture motion of the user may be finally determined according to data detected by the sensors, and then the sensors may transfer detected gesture information to the information processing apparatus. It should be noted that, after acquiring the gesture information of the user and generating a corresponding operation instruction, the information processing apparatus does not need to transfer the operation instruction to the smartwatch by using a wireless communications module or a Bluetooth module, but only needs to transfer the operation instruction by using a communications line inside the smartwatch. In addition, after receiving the operation instruction, the smartwatch can also normally respond to the operation instruction. Therefore, in addition to the foregoing easy-to-memorize advantage, particularly, when the information processing device is an intelligent terminal integrating the foregoing information processing apparatus and the terminal function, for example, a portable intelligent terminal, input accuracy can also be improved. A smartwatch is used as an example of the portable intelligent terminal. An input interface of the smartwatch is relatively small because of portability of the smartwatch. Entering a phone number is used as an example. When digits 1, 2, ..., 9, and 0 are entered by using a finger, the digits cannot be accurately entered usually because the input interface is small.

[0137] However, by using the information processing method in this embodiment of the present invention, each digit has a piece of fixed corresponding gesture information. Therefore, a digit that the user wants to enter can be accurately determined by identifying the gesture information of the user, thereby greatly reducing or even avoiding a case in which the user cannot accurately enter information.

[0138] FIG. 14 is a schematic structural diagram of an

information processing device according to an embodiment of the present invention. As shown in FIG. 14, an information processing device 140 may include: a sensor 1401, a processor 1402, a communications apparatus 1403, a memory 1404, and a bus 1405.

[0139] The sensor 1401, the processor 1402, the communications apparatus 1403, and the memory 1404 complete mutual communication through the bus 1405.

[0140] The sensor 1401 is configured to collect gesture information of a user. The sensor 1401 may be a contact sensor, a pressure sensor, or a biological electrostatic sensor. As long as a sensor can detect different modes enabling gesture information and gesture information of the user, the sensor may be applied in this embodiment.

[0141] The memory 1404 is configured to store a group of program instructions.

[0142] The memory may be a high-speed RAM memory, or may be a non-volatile memory (non-volatile memory), for example, at least one magnetic disk memory.

[0143] The processor 1402 is configured to invoke the program instructions stored in the memory 1404 to:

acquiring mode-enabling gesture information of a user, where the mode-enabling gesture information may be detected by the sensor and then transferred to the processor 1402;

enabling an input mode corresponding to the mode-enabling gesture information, where the input mode includes a keyboard input mode and a mouse input mode;

acquiring gesture information of the user in the input mode, where the gesture information includes tap-gesture information and/or slide-gesture information; and

generating, according to a preset correspondence between gesture information and an operation instruction, an operation instruction corresponding to the gesture information.

[0144] In this embodiment, there may be multiple input modes for the user, and each input mode is corresponding to one mode-enabling gesture. In this way, the processor 1402 may automatically identify, according to mode-enabling gesture information input by the user, an input mode currently wanted by the user, which facilitates use for the user.

[0145] The keyboard input mode indicates that in this mode, the user may directly trigger a character on a known keyboard by tapping a part of a finger, where the character may be a digit, an English letter, or a symbol with a fixed function, for example, a "#" key. Certainly, it is required to preconfigure a correspondence between gesture information of tapping or triggering a part of a finger by the user and each key of the known keyboard.

[0146] It should be noted that, for same gesture information, different processing and response results may be obtained in different input modes, and a piece of gesture information may be processed and responded to in

an input mode, but may not be processed and responded to in another input mode.

[0147] The processor 1402 may be a central processing unit(CPU) or an application-specific integrated circuit ASIC (Application-Specific Integrated Circuit), or is one or more integrated circuits configured to implement this embodiment of the present invention.

[0148] The communications apparatus 1403 is configured to receive data in a service operation task.

[0149] The communications apparatus 1403 may be specifically a wireless communications apparatus or a Bluetooth apparatus, so that the operation instruction generated by the processor 1402 is transferred to a terminal by using the wireless communications apparatus or the Bluetooth apparatus, and the terminal can respond to the operation instruction.

[0150] FIG. 15 is a schematic structural diagram of another information processing device according to an embodiment of the present invention. As shown in FIG. 15, an intelligent terminal 150 may include: a sensor 1501, a processor 1502, a memory 1503, and a bus 1504.

[0151] The sensor 1501, the processor 1502, and the memory 1503 complete mutual communication through the bus 1504.

[0152] The sensor 1501 is configured to collect gesture information of a user. The sensor 1501 may be a contact sensor, a pressure sensor, or a biological electrostatic sensor. As long as a sensor can detect different mode-enabling gesture information and gesture information of the user, the sensor may be applied in this embodiment.

[0153] The memory 1503 is configured to store a group of program instructions.

[0154] The memory may be a high-speed RAM memory, or may be a non-volatile memory (non-volatile memory), for example, at least one magnetic disk memory.

[0155] The processor 1502 is configured to invoke the program instructions stored in the memory 1503:

- acquiring mode-enabling gesture information of a user, where the mode-enabling gesture information may be detected by the sensor;
- enabling an input mode corresponding to the mode-enabling gesture information, where the input mode includes a keyboard input mode and a mouse input mode;
- acquiring gesture information of the user in the input mode, where the gesture information includes tap-gesture information and/or slide-gesture information;
- generating, according to a preset correspondence between gesture information and an operation instruction, an operation instruction corresponding to the gesture information; and
- responding to the operation instruction.

[0156] In this embodiment, there may be multiple input modes for the user, and each input mode is corresponding to one mode-enabling gesture. In this way, the proc-

essor 1502 may automatically identify, according to mode-enabling gesture information input by the user, an input mode currently wanted by the user, which facilitates use for the user.

[0157] The keyboard input mode indicates that in this mode, the user may directly trigger a character on a known keyboard by tapping a part of a finger, where the character may be a digit, an English letter, or a symbol with a fixed function, for example, a "#" key. Certainly, it is required to preconfigure a correspondence between gesture information of tapping or triggering a part of a finger by the user and each key of the known keyboard.

[0158] It should be noted that, for same gesture information, different processing and response results may be obtained in different input modes, and a piece of gesture information may be processed and responded to in an input mode, but may not be processed and responded to in another input mode.

[0159] The processor 1502 may be a central processing unit CPU or an application-specific integrated circuit ASIC (Application Specific Integrated Circuit), or is one or more integrated circuits configured to implement this embodiment of the present invention.

[0160] The information processing device is integrated into the terminal. Therefore, after acquiring the gesture information of the user and generating a corresponding operation instruction, the processor does not need to transfer the operation instruction to the portable intelligent terminal by using a wireless communications module or a Bluetooth module, but only needs to transfer the operation instruction by using a communications line inside the portable intelligent terminal.

[0161] In addition, after receiving the operation instruction, the processor of the portable intelligent terminal can also normally respond to the operation instruction. In addition, when the information processing device is an information processing device integrating the foregoing information processing apparatus and a terminal function, for example, a portable intelligent terminal, input accuracy may also be improved.

[0162] The embodiments in this specification are all described in a progressive manner, for same or similar parts in the embodiments, reference may be made to these embodiments, and each embodiment focuses on a difference from other embodiments. The apparatus disclosed in the embodiment is basically similar to the method disclosed in the embodiment, and therefore is described briefly; for related parts, reference may be made to partial descriptions of the method.

[0163] It should further be noted that in this specification, relational terms such as first and second are only used to distinguish one entity or operation from another, and do not necessarily require or imply that any actual relationship or sequence exists between these entities or operations.

[0164] Moreover, the terms "include", "include", or their any other variant is intended to cover a non-exclusive inclusion, so that a process, a method, an article, or a

device that includes a list of elements not only includes those elements but also includes other elements that are not expressly listed, or further includes elements inherent to such a process, method, article, or device. An element preceded by "includes a..." does not, without more constraints, preclude the presence of additional identical elements in the process, method, article, or device that includes the element.

[0165] In combination with the embodiments disclosed in this specification, method or algorithm steps may be implemented by hardware, a software module executed by a processor, or a combination thereof. The software module may be configured in a random access memory (RAM), a memory, a read-only memory (ROM), an electrically programmable ROM, an electrically erasable programmable ROM, a register, a hard disk, a removable disk, a CD-ROM, or a storage medium in any other forms well-known in the art.

[0166] The embodiments disclosed are described in the foregoing to enable a person skilled in the art to implement or use the present invention. Various modifications to the embodiments are obvious to the person skilled in the art, and general principles defined in this specification may be implemented in other embodiments without departing from the scope of the present invention. Therefore, the present invention will not be limited to the embodiments described in this specification but extends to the widest scope that complies with the principles and novelty disclosed in this specification.

Claims

1. An information processing method for controlling an input mode of a processing apparatus (80), the method comprising the steps:

acquiring (101), by a first acquiring module (801) in the processing apparatus (80), mode-enabling gesture information of a user;

enabling (102), by a mode enabling module (802) in the processing apparatus (80), an input mode corresponding to the mode-enabling gesture information, wherein the input mode comprises a keyboard input mode and a mouse input mode;

acquiring (103), by a second acquiring module (803) in the processing apparatus (80), gesture information of the user in the input mode, wherein the gesture information comprises tap-gesture information and/or slide-gesture information; and

generating (104), by an instruction generating module (804) in the processing apparatus (80), according to a preset correspondence between gesture information and an operation instruction, an operation instruction corresponding to the gesture information,

wherein the mode-enabling gesture information and the gesture information is detected by a sensor comprised in the processing apparatus (80), wherein the sensor is disposed on a wrist or a palm of the user; and
wherein the enabling (102) an input mode corresponding to the mode-enabling gesture information comprises:

enabling, by a first mode enabling module in the mode enabling module (802), the keyboard input mode when the mode-enabling gesture information is corresponding to a gesture of extending an index finger, a middle finger, a ring finger, and a little finger of the user; and

enabling, by a second mode enabling module in the mode enabling module (802), the mouse input mode when the mode-enabling gesture information is corresponding to a gesture of curling the index finger, the middle finger, the ring finger, and the little finger toward the palm of the user.

2. The information processing method according to claim 1, wherein when the input mode is the keyboard input mode, there is a one-to-one correspondence between 12 finger joints or finger phalanxes of an index finger, a middle finger, a ring finger, and a little finger of a user and 12 keys of a 12-key keypad; the acquiring gesture information of the user in the input mode comprises: acquiring (602), by the second acquiring module (803), in the keyboard input mode, tap-gesture information of tapping any finger joint or finger phalanx of the index finger, the middle finger, the ring finger, and the little finger by the user; and

correspondingly, the generating, according to a preset correspondence between gesture information and an operation instruction, an operation instruction corresponding to the gesture information comprises: generating (603), by the instruction generating module (804), according to a preset correspondence between tap-gesture information and an operation instruction, an operation instruction corresponding to the tap-gesture information.

3. The information processing method according to claim 1, wherein when the input mode is the mouse input mode, the acquiring gesture information of the user in the input mode comprises:

acquiring (702), by the second acquiring module (803), in the mouse input mode, slide-gesture information of sliding on an index finger, a middle finger, a ring finger, and a little finger of the user and/or tap-gesture information of tapping a finger joint or a finger phalanx; and

correspondingly, the generating, according to a preset correspondence between gesture information and an operation instruction, an operation instruction corresponding to the gesture information comprises: generating (703), by the instruction generating module (804), according to a preset correspondence between slide-gesture information and/or tap-gesture information and an operation instruction, an operation instruction corresponding to the slide-gesture information and/or the tap-gesture information.

4. The information processing method according to claim 3, wherein the slide-gesture information is corresponding to movement track information of a mouse pointer, and the tap-gesture information is corresponding to trigger information of a left or right mouse button.

5. The information processing method according to claim 1, wherein the acquiring mode-enabling gesture information of a user or the acquiring gesture information of the user in the input mode comprises:

acquiring (301) a pressure value of each part of the wrist or of each part of the palm when the sensor disposed on the wrist or the palm of the user detects an input mode-enabling gesture motion or a gesture motion of the user; determining (302) a displacement value of the sensor on the wrist or the palm of the user according to the pressure value; and determining (303), according to the displacement value, mode-enabling gesture information input by the user.

6. An information processing apparatus (80), comprising:

a first acquiring module (801), configured to acquire mode-enabling gesture information of a user; a mode enabling module (802), configured to enable an input mode corresponding to the mode-enabling gesture information, wherein the input mode comprises a keyboard input mode and a mouse input mode; a second acquiring module (803), configured to acquire gesture information of the user in the input mode, wherein the gesture information comprises tap-gesture information and/or slide-gesture information; and an instruction generation module (804), configured to generate, according to a preset correspondence between gesture information and an operation instruction, an operation instruction corresponding to the gesture information, wherein the mode-enabling gesture information

and the gesture information is detected by a sensor comprised by the processing apparatus (80), wherein the sensor is disposed on a wrist or a palm of the user; and wherein the mode enabling module (802) comprises:

a first mode enabling module, configured to enable the keyboard input mode when the mode-enabling gesture information is corresponding to a gesture of extending an index finger, a middle finger, a ring finger, and a little finger of the user; and a second mode enabling module, configured to enable the mouse input mode when the mode-enabling gesture information is corresponding to a gesture of curling the index finger, the middle finger, the ring finger, and the little finger toward the palm of the user.

7. The information processing apparatus (80) according to claim 6, wherein when the input mode is the keyboard input mode, there is a one-to-one correspondence between 12 finger joints or finger phalanxes of an index finger, a middle finger, a ring finger, and a little finger of a user and 12 keys of a 12-key keypad; the second acquiring module (803) is specifically configured to: acquire, in the keyboard input mode, tap-gesture information of tapping any finger joint or finger phalanx of the index finger, the middle finger, the ring finger, and the little finger by the user.

8. The information processing apparatus (80) according to claim 6, wherein when the input mode is the mouse input mode, the second acquiring module (803) is specifically configured to: acquire, in the mouse input mode, slide-gesture information of sliding on an index finger, a middle finger, a ring finger, and a little finger of the user and/or tap-gesture information of tapping a finger joint or a finger phalanx.

9. The information processing apparatus (80) according to claim 8, wherein the slide-gesture information is corresponding to movement track information of a mouse pointer, and the tap-gesture information is corresponding to trigger information of a left or right mouse button.

10. The information processing apparatus (80) according to claim 6, wherein the first acquiring module (801) or the second acquiring module (803) comprises:

an acquiring submodule, configured to acquire a pressure value of each part of the wrist or

of each part of the palm when the sensor disposed on the wrist or the palm of the user detects an input mode-enabling gesture motion or a gesture motion of the user; 5
a calculation module, configured to determine a displacement value of the sensor on the wrist or the palm of the user according to the pressure value; and
a gesture determining module, configured to determine, according to the displacement value, 10 mode-enabling gesture information input by the user.

Patentansprüche

1. Informationsverarbeitungsverfahren zum Steuern eines Eingabemodus einer Verarbeitungsvorrichtung (80), das Verfahren die folgenden Schritte aufweisend:

Erfassen (101), durch ein erstes Erfassungsmodul (801) in der Verarbeitungsvorrichtung (80), von modusaktivierender Gebärdeninformation eines Benutzers; 25
Aktivieren (102), durch ein Modusaktivierungsmodul (802) in der Verarbeitungsvorrichtung (80), eines Eingabemodus, der der modusaktivierenden Gebärdeninformation entspricht, wobei der Eingabemodus einen Tastatureingabemodus und einen Mauseingabemodus aufweist; 30
Erfassen (103), durch ein zweites Erfassungsmodul (803) in der Verarbeitungsvorrichtung (80), von Gebärdeninformation des Benutzers im Eingabemodus, wobei die Gebärdeninformation Klopfgebärdeninformation und/oder Gleitgebärdeninformation aufweist; und
Erzeugen (104), durch ein Befehlserzeugungsmodul (804) in der Verarbeitungsvorrichtung (80), gemäß einer voreingestellten Entsprechung zwischen Gebärdeninformation und einem Betriebsbefehl, eines Betriebsbefehls, der der Gebärdeninformation entspricht, 35
wobei die modusaktivierende Gebärdeninformation und die Gebärdeninformation durch einen Sensor erkannt wird, der in der Verarbeitungsvorrichtung (80) enthalten ist, wobei der Sensor an einem Handgelenk oder einer Handfläche des Benutzers angeordnet ist; und
wobei das Aktivieren (102) eines Eingabemodus entsprechend der modusaktivierenden Gebärdeninformation aufweist:

Aktivieren, durch ein erstes Modusaktivierungsmodul im Modusaktivierungsmodul (802), des Tastatureingabemodus, wenn die modusaktivierende Gebärdeninformati-

on einer Gebärde des Ausstreckens eines Zeigefingers, eines Mittelfingers, eines Ringfingers und eines kleinen Fingers des Benutzers entspricht; und
Aktivieren, durch ein zweites Modusaktivierungsmodul im Modusaktivierungsmodul (802), des Mauseingabemodus, wenn die modusaktivierende Gebärdeninformation einer Gebärde des Krümmens des Zeigefingers, des Mittelfingers, des Ringfingers und des kleinen Fingers zur Handfläche des Benutzers hin entspricht.

2. Informationsverarbeitungsverfahren nach Anspruch 1, wobei, wenn der Eingabemodus der Tastatureingabemodus ist, eine Eins-zu-Eins-Entsprechung zwischen 12 Fingergelenken oder Fingergliedern eines Zeigefingers, eines Mittelfingers, eines Ringfingers und eines kleinen Fingers eines Benutzers und 12 Tasten eines zwölfstastigen Tastenfelds vorliegt; wobei das Erfassen von Gebärdeninformation des Benutzers im Eingabemodus aufweist:

Erfassen (602), durch das zweite Erfassungsmodul (803), im Tastatureingabemodus, von Klopfgebärdeninformation des Klopfens von jeglichem Fingergelenk oder Fingerglied des Zeigefingers, des Mittelfingers, des Ringfingers und des kleinen Fingers durch den Benutzer; und
wobei entsprechend das Erzeugen, gemäß einer voreingestellten Entsprechung zwischen Gebärdeninformation und einem Betriebsbefehl, eines Betriebsbefehls, der der Gebärdeninformation entspricht, aufweist:
Erzeugen (603), durch das Befehlserzeugungsmodul (804), gemäß einer voreingestellten Entsprechung zwischen Klopfgebärdeninformation und einem Betriebsbefehl, eines Betriebsbefehls, der der Klopfgebärdeninformation entspricht.

3. Informationsverarbeitungsverfahren nach Anspruch 1, wobei, wenn der Eingabemodus der Mauseingabemodus ist, das Erfassen von Gebärdeninformation des Benutzers im Eingabemodus aufweist:

Erfassen (702), durch das zweite Erfassungsmodul (803), im Mauseingabemodus, von Gleitgebärdeninformation des Gleitens auf einem Zeigefinger, einem Mittelfinger, einem Ringfinger und einem kleinen Finger des Benutzers und/oder von Klopfgebärdeninformation des Klopfens eines Fingergelenks oder eines Fingerglieds; und
wobei entsprechend das Erzeugen, gemäß einer voreingestellten Entsprechung zwischen Gebärdeninformation und einem Betriebsbe-

- fehl, eines Betriebsbefehls, der der Gebärdensinformation entspricht, aufweist:
Erzeugen (703), durch das Befehlserzeugungsmodul (804), gemäß einer voreingestellten Entsprechung zwischen Gleitgebärdensinformation und/oder Klopfgärdensinformation und einem Betriebsbefehl, eines Betriebsbefehls, der der Gleitgebärdensinformation und/oder der Klopfgärdensinformation entspricht.
4. Informationsverarbeitungsverfahren nach Anspruch 3, wobei die Gleitgebärdensinformation Bewegungsverfolgungsinformation eines Mauszeigers entspricht und die Klopfgärdensinformation Ansteuerinformation einer linken oder rechten Maustaste entspricht. 15
5. Informationsverarbeitungsverfahren nach Anspruch 1, wobei das Erfassen von modusaktivierender Gebärdensinformation eines Benutzers oder das Erfassen von Gebärdensinformation des Benutzers im Eingabemodus aufweist:
Erfassen (301) eines Druckwerts von jedem Teil des Handgelenks oder von jedem Teil der Handfläche, wenn der Sensor, der am Handgelenk oder an der Handfläche des Benutzers angeordnet ist, eine eingabemodusaktivierende Gebärdensbewegung oder eine Gebärdensbewegung des Benutzers erkennt; Bestimmen (302) einer Verschiebung des Sensors am Handgelenk oder an der Handfläche des Benutzers gemäß dem Druckwert; und Bestimmen (303), gemäß dem Verschiebungswert, von modusaktivierender Gebärdensinformationseingabe durch den Benutzer. 20 25 30 35
6. Informationsverarbeitungsvorrichtung (80), aufweisend:
ein erstes Erfassungsmodul (801), das zum Erfassen von modusaktivierender Gebärdensinformation eines Benutzers konfiguriert ist; ein Modusaktivierungsmodul (802), das zum Aktivieren eines Eingabemodus, der der modusaktivierenden Gebärdensinformation entspricht, konfiguriert ist, wobei der Eingabemodus einen Tastatureingabemodus und einen Mauseingabemodus aufweist; ein zweites Erfassungsmodul (803), das zum Erfassen von Gebärdensinformation des Benutzers im Eingabemodus konfiguriert ist, wobei die Gebärdensinformation Klopfgärdensinformation und/oder Gleitgebärdensinformation aufweist; und ein Befehlserzeugungsmodul (804), das zum Erzeugen, gemäß einer voreingestellten Entsprechung zwischen Gebärdensinformation und einem Betriebsbefehl, eines Betriebsbefehls, der der Gleitgebärdensinformation und/oder der Klopfgärdensinformation entspricht, konfiguriert ist,
wobei die modusaktivierende Gebärdensinformation und die Gebärdensinformation durch einen Sensor erkannt wird, der in der Verarbeitungsvorrichtung (80) enthalten ist, wobei der Sensor an einem Handgelenk oder einer Handfläche des Benutzers angeordnet ist; und wobei das Modusaktivierungsmodul (802) aufweist:
- ein erstes Modusaktivierungsmodul, das zum Aktivieren des Tastatureingabemodus konfiguriert ist, wenn die modusaktivierende Gebärdensinformation einer Gebärde des Ausstreckens eines Zeigefingers, eines Mittelfingers, eines Ringfingers und eines kleinen Fingers des Benutzers entspricht; und
ein zweites Modusaktivierungsmodul, das zum Aktivieren des Mauseingabemodus konfiguriert ist, wenn die modusaktivierende Gebärdensinformation einer Gebärde des Krümmens des Zeigefingers, des Mittelfingers, des Ringfingers und des kleinen Fingers zur Handfläche des Benutzers hin entspricht.
7. Informationsverarbeitungsvorrichtung (80) nach Anspruch 6, wobei, wenn der Eingabemodus der Tastatureingabemodus ist, eine Eins-zu-Eins-Entsprechung zwischen 12 Fingergelenken oder Fingergliedern eines Zeigefingers, eines Mittelfingers, eines Ringfingers und eines kleinen Fingers eines Benutzers und 12 Tasten eines zwölftastigen Tastenfelds vorliegt; wobei das zweite Erfassungsmodul (803) spezifisch konfiguriert ist zum:
Erfassen, im Tastatureingabemodus, von Klopfgärdensinformation des Klopfens von jeglichem Fingergelenk oder Fingerglied des Zeigefingers, des Mittelfingers, des Ringfingers und des kleinen Fingers durch den Benutzer.
8. Informationsverarbeitungsvorrichtung (80) nach Anspruch 6, wobei, wenn der Eingabemodus der Mauseingabemodus ist, das zweite Erfassungsmodul (803) spezifisch konfiguriert ist zum:
Erfassen, im Mauseingabemodus, von Gleitgebärdensinformation des Gleitens auf einem Zeigefinger, einem Mittelfinger, einem Ringfinger und einem kleinen Finger des Benutzers und/oder von Klopfgärdensinformation des Klopfens eines Fingergelenks oder eines Fingerglieds.
9. Informationsverarbeitungsvorrichtung (80) nach Anspruch 8, wobei die Gleitgebärdensinformation Bewegungsverfolgungsinformation eines Mauszeigers

entspricht und die Klopfgärdeninformation Ansteuerinformation einer linken oder rechten Maustaste entspricht.

- 10.** Informationsverarbeitungsvorrichtung (80) nach Anspruch 6, wobei das erste Erfassungsmodul (801) oder das zweite Erfassungsmodul (803) aufweist:

ein Erfassungsnebenmodul, das zum Erfassen eines Druckwerts von jedem Teil des Handgelenks oder von jedem Teil der Handfläche konfiguriert ist, wenn der Sensor, der am Handgelenk oder an der Handfläche des Benutzers angeordnet ist, eine eingabemodusaktivierende Gebärdenbewegung oder eine Gebärdenbewegung des Benutzers erkennt; 10
 ein Berechnungsmodul, das zum Bestimmen einer Verschiebung des Sensors am Handgelenk oder an der Handfläche des Benutzers gemäß dem Druckwert konfiguriert ist; und 15
 ein Gebärdenbestimmungsmodul, das zum Bestimmen, gemäß dem Verschiebungswert, von modusaktivierender Gebärdeninformationseingabe durch den Benutzer konfiguriert ist. 20

Revendications

- 1.** Procédé de traitement d'informations pour commander un mode d'entrée d'un appareil de traitement (80), le procédé comprenant les étapes suivantes :

acquisition (101), par un premier module d'acquisition (801) dans l'appareil de traitement (80), d'informations de geste d'activation de mode d'un utilisateur ; 30
 activation (102), par un module d'activation de mode (802) dans l'appareil de traitement (80), d'un mode d'entrée correspondant aux informations de geste d'activation de mode, le mode d'entrée comprenant un mode d'entrée par clavier et un mode d'entrée par souris ; 35
 acquisition (103), par un deuxième module d'acquisition (803) dans l'appareil de traitement (80), d'informations de geste de l'utilisateur dans le mode d'entrée, les informations de geste comprenant des informations de geste de type tape et/ou des informations de geste de type glissement ; et 40
 génération (104), par un module générateur d'instruction (804) dans l'appareil de traitement (80), selon une correspondance préétablie entre des informations de geste et une instruction d'opération, d'une instruction d'opération correspondant aux informations de geste, les informations de geste d'activation de mode et les informations de geste étant détectées par un capteur contenu dans l'appareil de traitement 45
 50
 55

(80), le capteur étant placé sur un poignet ou une paume de l'utilisateur ; et l'étape d'activation (102) d'un mode d'entrée correspondant aux informations de geste d'activation de mode comprenant les étapes suivantes :

activation, par un premier module d'activation de mode dans le module d'activation de mode (802), du mode d'entrée par clavier lorsque les informations de geste d'activation de mode correspondent à un geste d'extension d'un index, d'un majeur, d'un annulaire et d'un auriculaire de l'utilisateur ; et

activation, par un deuxième module d'activation de mode dans le module d'activation de mode (802), du mode d'entrée par souris lorsque les informations de geste d'activation de mode correspondent à un geste de flexion de l'index, du majeur, de l'annulaire et de l'auriculaire vers la paume de l'utilisateur.

- 25 2.** Procédé de traitement d'informations selon la revendication 1, dans lequel, lorsque le mode d'entrée est le mode d'entrée par clavier, il existe une correspondance biunivoque entre 12 articulations de doigt ou phalanges de doigt d'un index, d'un majeur, d'un annulaire et d'un auriculaire d'un utilisateur et 12 touches d'un pavé de touches à 12 touches ; l'étape d'acquisition d'informations de geste de l'utilisateur dans le mode d'entrée comprend l'étape suivante : acquisition (602), par le deuxième module d'acquisition (803), dans le mode d'entrée par clavier, d'informations de geste de type tape relatives à une tape, par l'utilisateur, d'une articulation de doigt ou phalange de doigt quelconque de l'index, du majeur, de l'annulaire et de l'auriculaire ; et de façon correspondante, l'étape de génération, selon une correspondance préétablie entre des informations de geste et une instruction d'opération, d'une instruction d'opération correspondant aux informations de geste comprend l'étape suivante : génération (603), par le module générateur d'instruction (804), selon une correspondance préétablie entre des informations de geste de type tape et une instruction d'opération, d'une instruction d'opération correspondant aux informations de geste de type tape.
- 3.** Procédé de traitement d'informations selon la revendication 1, dans lequel, lorsque le mode d'entrée est le mode d'entrée par souris, l'étape d'acquisition d'informations de geste de l'utilisateur dans le mode d'entrée comprend l'étape suivante :

acquisition (702), par le deuxième module d'ac-

- quisition (803), dans le mode d'entrée par souris, d'informations de geste de type glissement relatives à un glissement sur un index, un majeur, un annulaire et un auriculaire de l'utilisateur et/ou d'informations de geste de type tape relatives à une tape d'une articulation de doigt ou d'une phalange de doigt ; et
de façon correspondante, l'étape de génération, selon une correspondance préétablie entre des informations de geste et une instruction d'opération, d'une instruction d'opération correspondant aux informations de geste comprend l'étape suivante :
génération (703), par le module générateur d'instruction (804), selon une correspondance préétablie entre des informations de geste de type glissement et/ou des informations de geste de type tape et une instruction d'opération, d'une instruction d'opération correspondant aux informations de geste de type glissement et/ou aux informations de geste de type tape.
4. Procédé de traitement d'informations selon la revendication 3, dans lequel les informations de geste de type glissement correspondent à des informations de suivi de mouvement d'un pointeur de souris, et les informations de geste de type tape correspondent à des informations de déclenchement d'un bouton gauche ou droit de souris.
5. Procédé de traitement d'informations selon la revendication 1, dans lequel l'étape d'acquisition d'informations de geste d'activation de mode d'un utilisateur ou l'étape d'acquisition d'informations de geste de l'utilisateur dans le mode d'entrée comprend les étapes suivantes :
- acquisition (301) d'une valeur de pression de chaque partie du poignet ou de chaque partie de la paume lorsque le capteur placé sur le poignet ou la paume de l'utilisateur détecte un mouvement de geste d'activation de mode d'entrée ou un mouvement de geste de l'utilisateur ;
détermination (302) d'une valeur de déplacement du capteur sur le poignet ou la paume de l'utilisateur selon la valeur de pression ; et
détermination (303), selon la valeur de déplacement, d'informations de geste d'activation de mode entrées par l'utilisateur.
6. Appareil de traitement d'informations (80), comprenant :
- un premier module d'acquisition (801), configuré pour acquérir des informations de geste d'activation de mode d'un utilisateur ;
un module d'activation de mode (802), configuré pour activer un mode d'entrée correspondant aux informations de geste d'activation de mode, le mode d'entrée comprenant un mode d'entrée par clavier et un mode d'entrée par souris ;
un deuxième module d'acquisition (803), configuré pour acquérir des informations de geste de l'utilisateur dans le mode d'entrée, les informations de geste comprenant des informations de geste de type tape et/ou des informations de geste de type glissement ; et
un module de génération d'instruction (804), configuré pour générer, selon une correspondance préétablie entre des informations de geste et une instruction d'opération, une instruction d'opération correspondant aux informations de geste,
les informations de geste d'activation de mode et les informations de geste étant détectées par un capteur contenu dans l'appareil de traitement (80), le capteur étant placé sur un poignet ou une paume de l'utilisateur ; et
le module d'activation de mode (802) comprenant :
- un premier module d'activation de mode, configuré pour activer le mode d'entrée par clavier lorsque les informations de geste d'activation de mode correspondent à un geste d'extension d'un index, d'un majeur, d'un annulaire et d'un auriculaire de l'utilisateur ; et
un deuxième module d'activation de mode, configuré pour activer le mode d'entrée par souris lorsque les informations de geste d'activation de mode correspondent à un geste de flexion de l'index, du majeur, de l'annulaire et de l'auriculaire vers la paume de l'utilisateur.
7. Appareil de traitement d'informations (80) selon la revendication 6, dans lequel, lorsque le mode d'entrée est le mode d'entrée par clavier, il existe une correspondance biunivoque entre 12 articulations de doigt ou phalanges de doigt d'un index, d'un majeur, d'un annulaire et d'un auriculaire d'un utilisateur et 12 touches d'un pavé de touches à 12 touches ; le deuxième module d'acquisition (803) est plus particulièrement configuré pour :
acquérir, dans le mode d'entrée par clavier, des informations de geste de type tape relatives à une tape, par l'utilisateur, d'une articulation de doigt ou phalange de doigt quelconque de l'index, du majeur, de l'annulaire et de l'auriculaire.
8. Appareil de traitement d'informations (80) selon la revendication 6, dans lequel, lorsque le mode d'entrée est le mode d'entrée par souris, le deuxième module d'acquisition (803) est plus particulièrement configuré pour :

acquérir, dans le mode d'entrée par souris, des informations de geste de type glissement relatives à un glissement sur un index, un majeur, un annulaire et un auriculaire de l'utilisateur et/ou des informations de geste de type tape relatives à une tape d'une articulation de doigt ou d'une phalange de doigt. 5

9. Appareil de traitement d'informations (80) selon la revendication 8, dans lequel les informations de geste de type glissement correspondent à des informations de suivi de mouvement d'un pointeur de souris, et les informations de geste de type tape correspondent à des informations de déclenchement d'un bouton gauche ou droit de souris. 10

10. Appareil de traitement d'informations (80) selon la revendication 6, dans lequel le premier module d'acquisition (801) ou le deuxième module d'acquisition (803) comprend :

un sous-module d'acquisition, configuré pour acquérir une valeur de pression de chaque partie du poignet ou de chaque partie de la paume lorsque le capteur placé sur le poignet ou la paume de l'utilisateur détecte un mouvement de 25
geste d'activation de mode d'entrée ou un mouvement de geste de l'utilisateur ;
un module de calcul, configuré pour déterminer une valeur de déplacement du capteur sur le poignet ou la paume de l'utilisateur selon la valeur de pression ; et 30
un module de détermination de geste, configuré pour déterminer, selon la valeur de déplacement, des informations de geste d'activation de mode entrées par l'utilisateur. 35
