ABSTRACT

A method is provided to control a hybrid powertrain, comprising a combustion engine; a gearbox with an input shaft connected to the combustion engine and an output shaft; a first planetary gear connected to the input shaft a second planetary gear connected to the first planetary gear; first and second electrical machines respectively connected to the first and second planetary gears; first gear pair connected with the first planetary gear and the output shaft; and second gear pair connected with the second planetary gear and the output shaft. The method comprises: a) engaging gears corresponding to the first gear pair and to the second gear pair; and b) connecting a second sun wheel, arranged in the second planetary gear and a second planetary wheel carrier with each other, with the use of a second coupling device.

METHOD FOR CONTROLLING A HYBRID VEHICLE DRIVELINE

CROSS-REFERENCE TO RELATED REFERENCE(S)

[0001] This application is a national stage application (filed under 35 §U.S.C. 371) of PCT/SE15/050298, filed Mar. 17, 2015 of the same title, which, in turn claims priority to Swedish Application No. 1450324-7, filed Mar. 20, 2014 of the same title; the contents of each of which are hereby incorporated by reference.

FIELD OF THE INVENTION

[0002] The present invention relates to a method, vehicle, and computer program product to control a hybrid powertrain.

BACKGROUND OF THE INVENTION

[0003] Hybrid vehicles may be driven by a primary engine, which may be a combustion engine, and a secondary engine, which may be an electrical machine. The electrical machine is equipped with at least one energy storage device, such as an electro-chemical energy storage device, for storage of electric power and control equipment to control the flow of electric power between the energy storage device and the electrical machine. The electrical machine may thus alternately operate as a motor and as a generator, depending on the vehicle's operating mode. When the vehicle is braked, the electrical machine generates electric power, which is stored in the energy storage device. This is usually referred to as regenerative braking, which entails that the vehicle is decelerated with the help of the electrical machine and the combustion engine. The stored electric power is used later for operation of the vehicle.

[0004] A gearbox in a hybrid vehicle may comprise a planetary gear. The planetary gearbox usually comprises three components, which are rotatably arranged in relation to each other, namely a sun wheel, a planetary wheel carrier and an internal ring gear. With knowledge about the number of cogs in the sun wheel and the internal ring gear, the mutual speeds of the three components may be determined during operation. One of the components of the planetary gear may be connected with an output shaft in a combustion engine. This component of the planetary gear thus rotates with a rotational speed corresponding to the rotational speed of the output shaft in the combustion engine. A second component in the planetary gear may be connected with an input shaft to a transmission device. This component of the planetary gear thus rotates with the same rotational speed as the input shaft to the transmission device. A third component in the planetary gear is used to achieve hybrid operation, connected with a rotor in an electrical machine. This component in the planetary gear thus rotates with the same rotational speed as the rotor of the electrical machine, if they are directly connected with each other. Alternatively, the electrical machine may be connected with the third component of the planetary gear via a transmission that has a gearing. In this case, the electrical machine and the third component in the planetary gear may rotate with different rotational speeds. The engine speed and/or the torque of the electrical machine may be controlled steplessly. During operating times when the input shaft to the transmission device must be provided with a desired rotational speed

and/or torque, a control device having knowledge about the engine speed of the combustion engine calculates the rotational speed with which the third component must be operated, in order for the input shaft to the gearbox to obtain the desired rotational speed. A control device activates the electrical machine, so that it provides the third component with the calculated engine speed and thus the input shaft to the transmission device with the desired rotational speed.

[0005] By connecting the combustion engine's output shaft, the electrical machine's rotor and the transmission device's input shaft with a planetary gear, the conventional clutch mechanism may be avoided. At acceleration of the vehicle, an increased torque must be delivered from the combustion engine and the electrical machine to the transmission device, and further to the vehicle's driving wheels. Since both the combustion engine and the electrical machine are connected with the planetary gear, the largest possible torque delivered by the combustion engine and the electrical machine will be limited by one of these drive units, namely the unit whose maximum torque is lower than the second drive unit's maximum torque, having regard to the gearing ratio between them. In case the electrical machine's highest torque is lower than the combustion engine's highest torque, having regard to the gearing between them, the electrical machine will not be able to generate a sufficiently large reaction torque to the planetary gear, entailing that the combustion engine may not transfer its highest torque to the transmission device and further to the vehicle's driving wheels. Thus, the highest torque that may be transferred to the transmission device is limited by the electrical machine's strength. This is also apparent from the so-called planet equation.

[0006] Using a conventional clutch, which disconnects the gearbox's input shaft from the combustion engine during shifting processes in the gearbox, entails disadvantages, such as heating of the clutch's discs, resulting in wear of the clutch discs and an increased fuel consumption. A conventional clutch mechanism is also relatively heavy and costly. It also occupies a relatively large space in the vehicle.

[0007] In a vehicle, the space available for the drive arrangement is often limited. If the drive arrangement comprises several components, such as a combustion engine, an electrical machine, a gearbox and a planetary gear, the construction must be compact. If there are additional components, such as a regenerative braking device, the requirements that the component parts must have a compact construction are even more stringent. At the same time, the component parts in the drive arrangement must be designed with dimensions that are able to absorb the required forces and torque.

[0008] For some types of vehicles, especially heavy goods vehicles and buses, a large number of gear steps is required. Thus, the number of component parts in the gearbox increases, which must also be dimensioned to be able to absorb large forces and torque arising in such heavy goods vehicles. This results in an increase of the size and weight of the gearbox.

[0009] There are also requirements for high reliability and high dependability of the components comprised in the drive device. In case the gearbox comprises multi-plate clutches, a wear arises, which impacts the reliability and life of the gearbox.

[0010] At regenerative braking, kinetic energy is converted into electric power, which is stored in an energy

storage device, such as accumulators. One factor impacting on the life of the energy storage device is the number of cycles in which the energy storage device provides and extracts power to and from the electric machines. The more cycles, the shorter the life of the energy storage device.

[0011] Under some operating conditions, it is desirable to shut off the combustion engine, with the objective of saving fuel and to avoid cooling down of the combustion engine's exhaust treatment system. The vehicle is then driven by the electrical machine. When a torque injection is required in the hybrid powertrain, or when the energy storage device must be charged, the combustion engine must be started quickly and efficiently.

[0012] In gearboxes with a large number of gear steps it is desirable, under some operating conditions, to be able to achieve a desired gear without passing all the gear steps in the gearbox and without any torque interruption in the powertrain.

[0013] The document EP-B1-1126987 shows a gearbox with double planetary gears. Each sun wheel of the planetary gear is connected to an electrical machine, and the internal wheels of the planetary gears are connected with each other. The planetary wheel carrier in each planetary gear is connected to a number of gear pairs, so that an infinite number of gear steps is obtained. Another document, EP-B1-1280677, also shows how the planetary gears may be bridged with a gear step arranged on the combustion engine's output shaft.

[0014] The document US-A1-20050227803 shows a vehicle transmission with two electrical machines, connected to the respective sun wheels in two planetary gears. The planetary gears have a common planetary wheel carrier, which is connected to the transmission's input shaft.

[0015] The document WO2008/046185-A1 shows a hybrid transmission with two planetary gears, wherein one electrical machine is connected to one of the planetary gears and a double clutch interacts with the second planetary gear. Both planetary gears also interact with each other via a cogwheel transmission.

SUMMARY OF THE INVENTION

[0016] Despite prior art solutions in the field, there is a need to further develop a method to control a hybrid powertrain, in order to achieve the desired gear with a small number of gear steps and without any torque interruption.

[0017] The objective of the invention is to provide a novel and advantageous method to reach the desired gear with a small number of gear steps, without any torque interruption in a hybrid powertrain.

[0018] Another objective of the invention is to provide a novel and advantageous computer program to control a hybrid powertrain.

[0019] The method provides an efficient and reliable method to control a hybrid powertrain, comprising a combustion engine; a gearbox with an input shaft and an output shaft, which combustion engine is connected to the input shaft; a first planetary gear, which is connected to the input shaft; a second planetary gear, connected to the first planetary gear; a first electrical machine, connected to the first planetary gear; a second electrical machine, connected to the second planetary gear; at least one gear pair connected with the first planetary gear and the output shaft; and at least one gear pair connected with the second planetary gear and the output shaft. The method comprises the steps: engaging

gears corresponding to the at least one gear pair, which is connected with the first planetary gear in the gearbox, and the gear pair, which is connected with the second planetary gear and the output shaft, and connecting two rotatable components in the second planetary gear with a second coupling device.

[0020] According to one embodiment of the invention, at least one gear pair, which is joined with the countershaft and the output shaft is connected, so that the countershaft is connected with the output shaft.

[0021] According to an additional embodiment of the invention, the at least one gear pair connected with a countershaft and the output shaft comprises a fifth and a sixth cogwheel in engagement with each other, which fifth cogwheel is arranged so that it may be connected with and disconnected from the countershaft with the use of a fifth coupling element, whereat the fifth cogwheel is connected with the countershaft.

[0022] According to an additional embodiment of the invention, the combustion engine is controlled in such a way that a synchronous rotational speed is achieved between the two rotatable components in the second planetary gear, following which the second coupling device is shifted, and locks two of the rotatable components of the second planetary gear with each other.

[0023] According to an additional embodiment of the invention, the at least one gear pair connected with the first planetary gear and the output shaft comprises a first pinion gear and a first cogwheel, engaged with each other, which first pinion gear is fixedly arranged with the first planetary gear, and which first cogwheel is arranged so that it may be connected with and disconnected from a countershaft; and a third pinion gear and a third cogwheel engaged with each other, which third pinion gear is fixedly arranged with the first planetary gear, and which third cogwheel is arranged so that it may be connected with and disconnected from the countershaft, whereat the first or the third cogwheel is connected with the countershaft.

[0024] According to an additional embodiment of the invention the at least one gear pair connected with the second planetary gear and the output shaft comprises a second pinion gear and also comprises a second cogwheel engaged with each other, which second pinion gear is fixedly arranged with the second planetary gear, and which second cogwheel is arranged so that it may be connected with and disconnected from a countershaft; and a fourth pinion gear and a fourth cogwheel engaged with each other, which fourth pinion gear is fixedly arranged with the second planetary gear and which fourth cogwheel is arranged so that it may be connected with and disconnected from the countershaft, whereat the second or the fourth cogwheel is connected to the countershaft.

[0025] According to another embodiment of the invention, the first electrical machine is activated in such a way that the first electrical machine generates a propulsion torque on the output shaft, via the at least one gear pair, which is connected with the first planetary gear and the output shaft, and via the at least one gear pair, which is connected with the countershaft and the output shaft;

[0026] the at least one gear pair, which is connected with the second planetary gear and the output shaft, is disconnected from the countershaft, by controlling the second electrical machine and the combustion engine, connected with the first planetary gear, in such a way that a substan-

tially zero torque state is achieved between the at least one gear pair, which is connected on the countershaft and which is connected with the second planetary gear and the output shaft, and the countershaft;

[0027] the at least one gear pair, which connected with the second planetary gear and the output shaft, is connected with the countershaft by controlling the combustion engine in such a way that a synchronous rotational speed is achieved between the at least one gear pair, connected with the second planetary gear and the output shaft which gear pair was not connected above, and the countershaft; and

[0028] the combustion engine and/or the second electrical machine is activated, so that the combustion engine and/or the second electrical machine generates a propulsion torque on the output shaft, via the at least one gear pair, connected with the second planetary gear and the output shaft.

[0029] According to another embodiment of the invention, gears are engaged, corresponding to the at least one gear pair, which is connected with the first planetary gear in the gearbox, and the gear pair, which is connected with the second planetary gear and the output shaft;

[0030] a coupling mechanism, which is arranged between the first planetary gear and the output shaft is locked, by controlling the combustion engine, in such a way that a synchronous rotational speed is achieved between the first planetary gear and the output shaft;

[0031] the first electrical machine is activated, so that the first electrical machine generates a propulsion torque on the output shaft, via the coupling mechanism;

[0032] the at least one gear pair, which is connected with the first planetary gear and the output shaft, is disconnected from the countershaft, by controlling the second electrical machine and the combustion engine, connected with the first planetary gear, so that a substantially zero torque state is achieved between the at least one gear pair, which is connected on the countershaft and which is connected with the first planetary gear and the output shaft, and the countershaft;

[0033] the at least one gear pair, which is connected with the first planetary gear and the output shaft, is connected with the countershaft, by controlling the combustion engine in such a way that a synchronous rotational speed is achieved between the at least one gear pair, which is connected with the first planetary gear and the output shaft, and the countershaft; and

[0034] the second electrical machine and the combustion engine, connected with the first planetary gear, are controlled to generate a propulsion torque on the output shaft.

[0035] The electrical machines, which are connected to the planetary gears, may generate power and/or supply torque depending on the desired operating mode. The electrical machines may also, at certain operating times, supply each other with power.

[0036] By connecting a first planetary wheel carrier in the first planetary gear, connected with a second sun wheel in the second planetary gear, a first sun wheel in the first planetary gear, connected with the first main shaft, and a second planetary wheel carrier in the second planetary gear connected with the second main shaft, a transmission that shifts gears without torque interruption may be obtained.

[0037] Suitably, a first planetary wheel carrier in the first planetary gear is directly connected with the combustion engine via the input shaft. Alternatively, the first planetary wheel carrier is connected with the combustion engine via a

coupling device. The second planetary wheel carrier in the second planetary gear is suitably directly connected with the second main shaft, and therefore with the transmission device. Thus, the hybrid powertrain may transfer a large torque in all operating modes, without being dependent on electric power from an energy storage device.

[0038] According to one embodiment, the first main shaft is connected with the first sun wheel, arranged in the first planetary gear. Alternatively, the first main shaft is connected with a first ring gear arranged in the first planetary gear.

[0039] According to one embodiment, the second planetary gear is connected to the first planetary gear by way of connecting the first planetary wheel carrier with a second sun wheel, arranged in the second planetary gear. Alternatively, both the planetary gears are connected to each other by way of the first planetary wheel carrier being connected with a second internal ring gear, arranged in the second planetary gear.

[0040] The gearbox may preferably be equipped with a number of gear pairs, comprising cogwheels that may be mechanically locked with and released from a countershaft. Thus, a number of fixed gear steps is obtained, which may be shifted without torque interruption. The cogwheels that may be locked on the countershaft also result in a compact construction with high reliability and high dependability. Alternatively, pinion gears in the gear pairs may be arranged to be lockable and disconnectable on the first and/or second main shaft.

[0041] With the gearbox according to the invention conventional slip clutches between the combustion engine and the gearbox may be avoided.

[0042] A locking mechanism is arranged to fixedly connect the combustion engine's output shaft with the gearbox housing. Thus, the first planetary wheel carrier will also be locked to the gearbox housing. By locking the combustion engine's output shaft with the locking mechanism and the first planetary wheel carrier with the gearbox's housing, the gearbox, and thus the vehicle, becomes adapted for electric operation by the electrical machines. The electrical machines thus emit a torque to the output shaft of the gearbox.

[0043] A first and second coupling device is arranged between the planetary wheel carrier and the sun wheel of the respective planetary gears. The task of the coupling devices is to lock the respective planetary wheel carriers with the sun wheel. When the planetary wheel carrier and the sun wheel are connected with each other, the power from the combustion engine will pass through the planetary wheel carrier, the coupling device, the sun wheel and further along to the gearbox, which entails that the planetary wheels do not absorb any torque. This entails that the dimension of the planetary wheels may be adapted only to the electrical machine's torque instead of the combustion engine's torque, which in turn means the planetary wheels may be designed with smaller dimensions. Thus, a drive arrangement according to the invention is obtained, which has a compact construction, a low weight and a low manufacturing cost.

[0044] The coupling devices and the locking mechanisms preferably comprise an annular sleeve, which is shifted axially between a connected and a disconnected state. The sleeve encloses, substantially concentrically, the gearbox's rotating components and is moved between the connected

and disconnected state with a power element. Thus, a compact construction is obtained, with a low weight and a low manufacturing cost.

[0045] In order to connect, with the first and the second coupling device, respectively, the sun wheel and the planetary wheel carrier of the respective planetary gear, the combustion engine and/or the first electrical machine and/or the second electrical machine is controlled in such a way that a synchronous rotational speed is achieved between the sun wheel and the planetary wheel carrier. When a synchronous rotational speed has been achieved, the coupling device is shifted, so that the sun wheel and the planetary wheel carrier become mechanically connected with each other.

[0046] In order to disconnect the respective planetary gear's planetary wheel carrier and sun wheel from each other, the first and/or second electrical machine is controlled, so that torque balance is achieved in the planetary gear. When torque balance has been achieved, the coupling device is shifted, so that the sun wheel and the planetary wheel carrier are no longer mechanically connected with to each other.

[0047] Torque balance relates to a state where a torque acts on an internal ring gear arranged in the planetary gear, representing the product of the torque acting on the planetary wheel carrier of the planetary gear and the gear ratio of the planetary gear, while simultaneously a torque acts on the planetary gear's sun wheel, representing the product of the torque acting on the planetary wheel carrier and (1—the planetary gear's gear ratio). In the event two of the planetary gear's component parts, i.e. the sun wheel, the internal ring gear or planetary wheel carriers, are connected with a coupling device, this coupling device does not transfer any torque between the planetary gear's parts when torque balance prevails. Accordingly, the coupling device may easily be shifted and the planetary gear's component parts be disconnected.

BRIEF DESCRIPTION OF THE DRAWINGS

[0048] Below is a description, as an example, of preferred embodiments of the invention with reference to the enclosed drawings, on which:

[0049] FIG. 1 schematically shows a vehicle in a side view with a combustion engine and a hybrid powertrain comprising a gearbox, which is controlled according to the present invention,

[0050] FIG. 2 shows a schematic side view of a hybrid powertrain with a gearbox, which is controlled according to the present invention,

[0051] FIG. 3 shows a simplified schematic view of the hybrid powertrain in FIG. 2, and

[0052] FIG. 4 shows a flow chart of the method to control a gearbox according to the present invention.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS OF THE INVENTION

[0053] FIG. 1 shows a schematic side view of a vehicle 1, comprising a gearbox 2 and a combustion engine 4, which are comprised in a hybrid powertrain 3. The combustion engine 4 is connected to the gearbox 2, and the gearbox 2 is further connected to the driving wheels 6 of the vehicle 1 via a propeller shaft 9. The driving wheels 6 are equipped with brake devices 7 to brake the vehicle 1.

[0054] FIG. 2 shows a schematic side view of a hybrid powertrain 3 with a gearbox 2, comprising an input shaft 8, a first and a second planetary gear 10 and 12, respectively, a first and a second electrical machine 14 and 16, respectively, a countershaft 18 and an output shaft 20. The hybrid powertrain comprises a combustion engine 4, connected to the gearbox 2. The combustion engine 4 is connected with the gearbox 2 via the input shaft 8 of the gearbox. The combustion engine has an output shaft 97. The output shaft 97 of the combustion engine 4 is connected to the input shaft of the gearbox 2. The first planetary gear 10 has a first internal ring gear 22, to which a first rotor 24 in the first electrical machine 14 is connected. The first planetary gear 10 also has a first sun wheel 26 and a first planetary wheel carrier 50. The first planetary wheel carrier 50 is connected with the combustion engine 4 via the input shaft 8 of the gearbox. The second planetary gear 12 has a second internal ring gear 28, to which a second rotor 30 of the second electrical machine 16 is connected. The second planetary gear 12 has a second sun wheel 32 and a second planetary wheel carrier 51. The first and the second sun wheels 26 and 32, respectively, are coaxially arranged, which, according to the embodiment displayed, entails that a first main shaft 34 arranged on the first sun wheel 26 extends inside a second main shaft 36, which is equipped with a central boring 38, arranged on the second planetary wheel carrier 51. It is also possible to arrange the first and second sun wheels 26 and 32, respectively, and also the first main shaft 34 and the second main shaft 36, in parallel with and next to each other. In this case, the countershaft 18 is suitably arranged between the first main shaft 34 and the second main shaft 36, and the torque may be extracted directly from the countershaft 18. The countershaft 18 thus constitutes, in this case, the output shaft 20.

[0055] The combustion engine 4 is connected with the first planetary wheel carrier 50, and the first planetary wheel carrier 50 is connected with the second sun wheel 32.

[0056] The first electrical machine 14 is equipped with a first stator 40, which is connected to the vehicle 1, via a gear housing 42 surrounding the gearbox 2. The second electrical machine 16 is equipped with a second stator 44, which is connected to the vehicle 1, via a gear housing 42 surrounding the gearbox 2. The first and the second electrical machine 16 are connected to an energy storage device 46, such as a battery, which, depending on the vehicle's 1 operating mode, operates the electrical machines 14 and 16, respectively. At other operating modes, the electrical machines 14 and 16, respectively, may work as generators, wherein power is supplied to the energy storage device 46. An electronic control device 48 is connected to the energy storage device 46 and controls the supply of power to the electrical machines 14 and 16, respectively. Preferably the energy storage device 46 is connected to the electrical machines 14 and 16, respectively, via a switch 49, which is connected to the control device 48. In some operating modes, the electrical machines 14 and 16, respectively, may also operate each other. Electric power is then led from one of the electrical machines 14, 16 to the second electrical machine 14, 16 via the switch 49, connected to the electrical machines 14, 16. Thus, it is possible to achieve a power balance between the electrical machines 14, 16. Another computer 53 may also be connected to the control device 48 and the gearbox 2.

[0057] The first planetary gear 10 is equipped with a first planetary wheel carrier 50, on which a first set of planetary wheels 52 is mounted. The second planetary gear 12 is equipped with a second planetary wheel carrier 51, on which a second set of planetary wheels 54 is mounted. The first set of planetary wheels 52 interacts with the first internal ring gear 22 and the first sun wheel 26. The second set of planetary wheels 54 interacts with the second internal ring gear 28 and the second sun wheel 32. The input shaft 8 of the gearbox 2 is connected with the first planetary wheel carrier 50.

[0058] A first coupling device 56 is arranged between the first sun wheel 26 and the first planetary wheel carrier 50. By arranging the first coupling device 56 in such a way that the first sun wheel 26 and the first planetary wheel carrier 50 are connected with each other, and may therefore not rotate in relation to each other, the first planetary wheel carrier 50 and the first sun wheel 26 will rotate with equal rotational speeds.

[0059] A second coupling device 58 is arranged between the second sun wheel 32 and the second planetary wheel carrier 51. By arranging the second coupling device 58 in such a way that the second sun wheel 32 and the second planetary wheel carrier 51 are connected with each other, and may therefore not rotate in relation to each other, the second planetary wheel carrier 51 and the second sun wheel 32 will rotate with equal rotational speeds.

[0060] Preferably, the first and second coupling devices 56, 58 comprise a first and a second splines-equipped coupling sleeve 55 and 57, respectively, which is axially shiftable on a splines-equipped section on the first and second, respectively, planetary wheel carrier 50 and 51, and on a splines-equipped section on the respective sun wheels 26 and 32. By shifting the respective coupling sleeve 55, 57 so that the splines-equipped sections are connected via the respective coupling sleeves 55, 57, the first planetary wheel carrier 50 and the first sun wheel 26, as well as the second planetary wheel carrier 51 and the second sun wheel 32, respectively, become mutually interlocked with each other and may not rotate in relation to each other.

[0061] The first and second coupling device 56, 58 according to the embodiment displayed in FIG. 2 are arranged between the first sun wheel 26 and the first planetary wheel carrier 50, and between the second sun wheel 28 and the second planetary wheel carrier 51, respectively. However, it is possible to arrange an additional or alternative coupling device (not displayed) between the first internal ring gear 22 and the first planetary wheel carrier 50, and also to arrange an additional or alternative coupling device (not displayed) between the second internal ring gear 28 and the second planetary wheel carrier 51.

[0062] The first planetary wheel carrier 50 of the first planetary gear 10 in this embodiment is fixedly connected with the second sun wheel 32 of the second planetary gear 12. Alternatively, the first planetary wheel carrier 50 is fixedly connected with the second internal ring gear 28 of the second planetary gear 12.

[0063] A transmission device 19, which comprises a first gear pair 60, arranged between the first planetary gear 10 and the output shaft 20 is connected to the first and the second main shaft 34, 36. The first gear pair 60 comprises a first pinion gear 62 and a first cogwheel 64, which are in engagement with each other. A second gear pair 66 is arranged between the second planetary gear 12 and the

output shaft 20. The second gear pair 66 comprises a second pinion gear 68 and a second cogwheel 70, which are in engagement with each other. A third gear pair 72 is arranged between the first planetary gear 10 and the output shaft 20. The third gear pair 72 comprises a third pinion gear 74 and a third cogwheel 76, which are in engagement with each other. A fourth gear pair 78 is arranged between the second planetary gear 12 and the output shaft 20. The fourth gear pair 78 comprises a fourth pinion gear 80 and a fourth cogwheel 82, which are in engagement with each other.

[0064] On the first main shaft 34, the first and the third pinion gears 62 and 74, respectively, are arranged. The first and the third pinion gears 62 and 74, respectively, are fixedly connected with the first main shaft 34, so that they may not rotate in relation to the first main shaft 34. On the second main shaft 36, the second and the fourth pinion gears 68 and 80, respectively, are arranged. The second and the fourth pinion gears 68 and 80, respectively, are fixedly connected with the second main shaft 36, so that they may not rotate in relation to the second main shaft 36.

[0065] The countershaft 18 extends substantially in parallel with the first and the second main shaft 34 and 36, respectively. On the countershaft 18, the first, second, third and fourth cogwheels 64, 70, 76 and 82, respectively, are mounted. The first pinion gear 62 engages with the first cogwheel 64, the second pinion gear 68 engages with the second cogwheel 70, the third pinion gear 74 engages with the third cogwheel 76 and the fourth pinion gear 80 engages with the fourth cogwheel 82.

[0066] The first, second, third and fourth cogwheels 64, 70, 76 and 82, respectively, may be individually locked with and released from the countershaft 18 with the assistance of the first, second, third and fourth coupling elements 84, 86, 88 and 90, respectively. The coupling elements 84, 86, 88 and 90, respectively, preferably consist of splines-equipped sections on the cogwheels 64, 70, 76 and 82, respectively, and on the countershaft 18, which interact with fifth and sixth coupling sleeves 83, 85 which engage mechanically with the splines-equipped sections of the respective first to fourth cogwheel 64, 70, 76 and 82 and of the countershaft 18. The first and third coupling elements 84, 88 are preferably equipped with a common coupling sleeve 83, and the second and fourth coupling elements 86, 90 are preferably equipped with a common coupling sleeve 85. In the released state, a relative rotation may occur between the cogwheels 64, 70, 76 and 82 and of the countershaft 18. The coupling elements 84, 86, 88 and 90, respectively, may also consist of friction clutches. On the countershaft 18 a fifth cogwheel 92 is also arranged, which engages with a sixth cogwheel 94, which is arranged on the output shaft 20 of the gearbox 2.

[0067] The countershaft 18 is arranged between the respective first and second planetary gears 10, 12 and the output shaft 20, so that the countershaft 18 is connected with the output shaft 20 via a fifth gear pair 21, which comprises the fifth and the sixth cogwheel 92, 94. The fifth cogwheel 92 is arranged so it may be connected with and disconnected from the countershaft 18 with a fifth coupling element 93.

[0068] By disconnecting the fifth cogwheel 92, which is arranged to be disconnectable from the countershaft 18, it is possible to transfer torque from the second planetary gear 12 to the countershaft 18 via, for example, the second gear pair 66, and to further transfer torque from the countershaft 18 to the output shaft 20 via, for example, the first gear pair 60. Thus, a number of gear steps is obtained, wherein torque

from one of the planetary gears **10**, **12** may be transferred to the countershaft **18**, and further along from the countershaft **18** to the main shaft **34**, **36** connected with the second planetary gear **10**, **12**, finally to transfer torque to the output shaft **20** of the gearbox **2**. This presumes, however, that a coupling mechanism **96** arranged between the first main shaft **34** and the output shaft **20** is connected, which is described in more detail below.

[0069] The fifth cogwheel **92** may be locked to and released from the countershaft **18** with the assistance of a fifth coupling element **93**. The coupling element **93** preferably consists of splines-equipped sections adapted on the fifth cogwheel **92** and the countershaft **18**, which sections interact with a ninth coupling sleeve **87**, which engages mechanically with the splines-equipped sections of the fifth cogwheel **92** and the countershaft **18**. In the released state, a relative rotation may occur between the fifth cogwheel **92** and the countershaft **18**. The fifth coupling element **93** may also consist of friction clutches.

[0070] Torque transfer from the input shaft **8** of the gearbox **2** to the output shaft **20** of the gearbox **2** may occur via the first or the second planetary gear **10** and **12**, respectively, and the countershaft **18**. The torque transfer may also occur directly via the first planetary gear **10**, whose first sun wheel **26** is connected, via the first main shaft **34**, to the output shaft **20** of the gearbox **2** via a coupling mechanism **96**. The coupling mechanism **96** preferably comprises a splines-equipped seventh coupling sleeve **100**, which is axially shiftable on the first main shaft **34** and on the splines-equipped sections of the output shaft **20**. By shifting the seventh coupling sleeve **100**, so that the splines-equipped sections are connected via the seventh coupling sleeve **100**, the first main shaft **34** becomes locked with the output shaft **20**, which, when rotating, will therefore have the same rotational speed. By disconnecting the fifth cogwheel **92** of the fifth gear pair **21** from the countershaft **18**, torque from the second planetary gear **12** may be transferred to the countershaft **18**, and further along from the countershaft **18** to the first main shaft **34**, connected with the first planetary gear **10**, in order finally to transfer torque via the coupling mechanism **96** to the output shaft **20** of the gearbox **2**.

[0071] In some operating modes the gearbox **2** may operate so that one of the sun wheels **26** and **32**, respectively, are locked with the first and the second planetary wheel carrier **50** and **51**, respectively, with the help of the first and the second coupling device **56** and **58**, respectively. The first and the second main shaft **34** and **36**, respectively, then obtain the same rotational speed as the input shaft **8** of the gearbox **2**, depending on which sun wheel **26** and **32**, respectively, is locked with the respective planetary wheel carriers **50** and **51**. One or both of the electrical machines **14** and **16**, respectively, may operate as a generator to generate electric power to the energy storage device **46**. Alternatively, the electrical machine **14** and **16**, respectively, may provide a torque injection, in order to thus increase the torque in the output shaft **20**. At some operating times, the electrical machines **14** and **16**, respectively, will supply each other with electric power, independently of the energy storage device **46**.

[0072] It is also possible that both the first and the second electrical machine **14** and **16**, respectively, generate power to the energy storage device **46**. At engine braking the driver releases the accelerator pedal (not displayed) of the vehicle

1. The output shaft **20** of the gearbox **2** then operates one or both electrical machines **14** and **16**, respectively, while the combustion engine **4** and the electrical machines **14** and **16**, respectively, engine brake. The electrical machines **14** and **16**, respectively, in this case generate electric power, which is stored in the energy storage device **46** in the vehicle **1**. This operating state is referred to as regenerative braking. In order to facilitate more powerful braking effect the output shaft **97** of the combustion engine's **4** may be locked and thus be prevented from rotating. Thus, only one of or both the electrical machines **14** and **16**, respectively, will function as brakes and **16** generate electric power, which is stored in the energy storage device **46**. The locking of the output shaft **97** of the combustion engine **4** may also be carried out when the vehicle must accelerate by only one or both the electrical machines **14** and **16**, respectively. If the torque of one or both of the respective electrical machines **14** and **16** overcomes the torque off the combustion engine **4**, and having regard to the gearing between them, the combustion engine **4** will not be able to resist the large torque which the respective electrical machines **14** and **16** generate, so that it becomes necessary to lock the output shaft **97** of the combustion engine's **4**. The locking of the output shaft **97** of the combustion engine **4** is preferably carried out with a locking device **102**, which is arranged between the first planetary wheel carrier **50** and the gear housing **42**. By locking the first planetary wheel carrier **50** and the gear housing **42**, the output shaft **97** of the combustion engine **4** will also be locked, since the output shaft **97** of the combustion engines **4** is connected with the first planetary wheel carrier **50** via the input shaft **8** of the gearbox. The locking device **102** preferably comprises a splines-equipped eighth coupling sleeve **104**, which is axially shiftable on a splines-equipped section of the first planetary wheel carrier **50**, and on a splines-equipped section of the gear housing. By shifting the eighth coupling sleeve **104** so that the splines-equipped sections are connected via the coupling sleeve **104**, the first planetary wheel carrier **50**, and therefore the output shaft **97** of the combustion engine **4** is prevented from rotating.

[0073] The control device **48** is connected to the electrical machines **14** and **16**, respectively, to control the respective electrical machines **14** and **16**, so that they, during certain operating times, use stored electric power to supply driving power to the output shaft **20** of the gearbox **2**, and during other operating times use the kinetic energy of the output shaft **20** of the gearbox **2** to extract and store electric power. The control device **48** thus detects the rotational speed and/or the torque of the output shaft **97** of the combustion engine **4** via sensors **98** arranged at the electrical machines **14** and **16**, respectively, and in the output shaft **20** of the gearbox **2**, in order thus to gather information and to control the electrical machines **14** and **16**, respectively, to operate as electric motors or generators. The control device **48** may be a computer with software suitable for this purpose. The control device **48** also controls the flow of power between the energy storage device **46** and the respective stators **40** and **44** of the electrical machines **14** and **16**, respectively. At times when the electrical machines **14** and **16**, respectively, operate as engines, stored electric power is supplied from the energy storage device **46** to the respective stators **40** and **44**. At times when the electrical machines **14** and **16** operate as generators electric power is supplied from the respective stators **40** and **44** to the energy storage device **46**. However,

as stated above, the electrical machines **14** and **16**, respectively, may, during certain operating times, supply each other with electric power, independently of the energy storage device **46**.

[0074] The first and the second coupling devices **56** and **58**, respectively, the first, second, third, fourth and fifth coupling elements **84**, **86**, **88**, **90** and **93**, respectively, the coupling mechanism **96** between the first main shaft **34** and the output shaft **20**, and the locking device **102** between the first planetary wheel carrier **50** and the gear housing **42**, are connected to the control device **48** via their respective coupling sleeves. These components are preferably activated and deactivated by electric signals from the control device **48**. The coupling sleeves are preferably shifted by non-displayed power elements, such as hydraulically or pneumatically operated cylinders. It is also possible to shift the coupling sleeves with electrically powered power elements.

[0075] The example embodiment in FIG. 2 shows four pinion gears **62**, **68**, **74** and **80**, respectively, and four cogwheels **64**, **70**, **76** and **82**, respectively, and two respective planetary gears **10** and **12**, with associated electrical machines **14** and **16**, respectively. However, it is possible to adapt the gearbox **2** with more or fewer pinion gears and cogwheels, and with more planetary gears with associated electrical machines.

[0076] FIG. 3 illustrates the hybrid powertrain **3** according to FIG. 2 in a simplified view, where some components have been excluded in the interest of clarity. **G1** in FIG. 3 consists of at least one gear pair connected with the first main shaft **34** and therefore with the first planetary gear **10**, and a gear pair **G2** consists of at least one gear pair connected with the second main shaft **36** and therefore with the second planetary gear **12**. These gear pairs **G1**, **G2** are also connected to the output shaft **20** via the countershaft **18**. **G1** and **G2**, respectively, may consist of one or several gear pairs. The gear pair **G1**, connected with the first planetary gear **10**, may for example consist of the first gear pair **60** and/or the third gear pair **72**, as described in FIG. 2. The gear pair **G2**, connected with the second planetary gear **12**, may for example consist of the second gear pair **66** and/or the fourth gear pair **78**, as described in FIG. 2. Further, at least one gear pair **G3**, connected with the output shaft **20** and the countershaft, **18** is displayed, which may consist of the fifth gear pair **21** described in FIG. 2. **G3** may consist of one or several gear pairs. Alternatively, torque may be extracted directly from the countershaft **18**, which thus constitutes the output shaft.

[0077] The at least one gear pair **G1**, **60**, **72**, connected with the first planetary gear **10** comprises at least one pinion gear **62**, **74** and one cogwheel **64**, **76** arranged in engagement with each other, which pinion gear **62**, **74** may be arranged in such a way that it may be connected with and disconnected from the main shaft **34**, arranged with the first planetary gear **10**. The at least one cogwheel **64**, **76** may be arranged so that it may be connected with and disconnected from the countershaft **18**.

[0078] The at least one gear pair **G2**, **66**, **78**, connected with the second planetary gear **12**, comprises at least one pinion gear **68**, **80** and one cogwheel **70**, **82** arranged in engagement with each other, which pinion gear **68**, **80** may be arranged in such a way that it may be connected with and disconnected from the second main shaft **36**, arranged with the first planetary gear **12**. The at least one cogwheel **70**, **82**

may be arranged so that it may be connected with and disconnected from the countershaft **18**.

[0079] As described, torque is extracted from the gearbox **2** from the output shaft **20**. It is also possible to extract torque directly from the first or second main shaft **34**, **36**, or directly from the countershaft **18**, which in this case constitutes the output shaft **20**. Torque may also be extracted in parallel from two or all of the three shafts **18**, **34**, **36** simultaneously.

[0080] Below, an up-shift from a first to a seventh gear will be described, wherein the gearbox **2** is arranged in a vehicle **1** and the vehicle is propelled by the combustion engine **4**. The description of the up-shift will comprise components that are not displayed in the simplified FIG. 3, but which are displayed in FIG. 2.

[0081] The input shaft **8** of the gearbox **2** is connected to the output shaft **97** of the vehicle's **1** combustion engine **4**. The output shaft **20** of the gearbox **2** is connected to a driving shaft **99** in the vehicle **1**. At idling of the combustion engine **4** and when the vehicle **1** is at a standstill, the input shaft **8** of the gearbox **2** rotates at the same time as the output shaft **20** of the gearbox **2** is at a standstill. The locking device **102** is deactivated, so that the output shaft **97** of the combustion engine **4** may rotate freely. Since the input shaft **8** of the gearbox **2** rotates, the first planetary wheel carrier **50** will also rotate, which entails that the first set of planetary wheels **52** will rotate. Since the first planetary wheel carrier **50** is connected to the second sun wheel **32**, the second sun wheel **32**, and thus also the second set of planetary wheels **54**, will rotate. By not supplying power to the first and the second electrical machines **14** and **16**, respectively, the first and the second internal rings **22** and **28**, respectively, which are connected with the respective first and second rotor **24** and **30** of the electrical machines **14** and **16**, respectively, will rotate freely, so that no torque is absorbed by the respective internal rings **22** and **28**. The first and the second coupling devices **56** and **58**, respectively, are disconnected and thus not actuated. Thus, no torque will be transferred from the combustion engine **4** to the sun wheel **26** of the first planetary gear **10** or to the planetary wheel carrier **51** of the second planetary gear **12**. The coupling mechanism **96** between the first main shaft **34** and the output shaft **20** is disconnected, so that the first main shaft **34** and the output shaft **20** may rotate freely in relation to each other. Since the first planetary gear's sun wheel **26**, the planetary wheel carrier **51** of the second planetary gear **12** and the output shaft **20** of the gearbox **2** are, at this stage, at a standstill, the countershaft **18** is also at a standstill. In a first step the fourth cogwheel **82** and the third cogwheel **76** are connected with the countershaft **18** with the assistance of the fourth and third coupling elements **90** and **88**, respectively. The first cogwheel **64** and the second cogwheel **70** are disconnected from the countershaft **18**. Thus, the first cogwheel **64** and the second cogwheel **70** are allowed to rotate freely in relation to the countershaft **18**. The fifth cogwheel **92** of the fifth gear pair **21** is locked on the countershaft **18** with the assistance of the fifth coupling element **93**.

[0082] In order to start the rotation of the output shaft **20** of the gearbox **2**, with the objective of driving the vehicle **1**, the fourth pinion gear **80** and the fourth cogwheel **82** on the countershaft **18** must be brought to rotate. This is achieved by making the second planetary wheel carrier **51** rotate. When the second planetary wheel carrier **51** rotates, the second main shaft **36** will also rotate and thus the fourth

pinion gear 80, which is arranged on the second main shaft 36, also rotates. The second planetary wheel carrier 51 is made to rotate by controlling the second internal ring gear 28 with the second electrical machine 16. By activating the second electrical machine 16 and controlling the combustion engine 4 to a suitable engine speed, the vehicle 1 begins to move as the second main shaft 36 begins to rotate. When the second planetary wheel carrier 51 and the second sun wheel 32 achieve the same rotational speed, the second sun wheel 32 is locked with the second planetary wheel carrier 51 with the assistance of the second coupling device 58. As mentioned above, the second coupling device 58 is preferably adapted in such a way that the second sun wheel 32 and the second planetary wheel carrier 51 engage mechanically with each other. Alternatively, the second coupling device 58 may be adapted as a slip brake or a multi-plate clutch which connects, in a smooth way, the second sun wheel 32 with the second planetary wheel carrier 51. When the second sun wheel 32 is connected with the second planetary wheel carrier 51, the second planetary wheel carrier 51 will rotate with the same rotational speed as the output shaft 97 of the combustion engine 4. Thus, the torque generated by the combustion engine 4 is transferred to the output shaft 20 of the gearbox 2 via the fourth pinion gear 80, the fourth cogwheel 82 on the countershaft 18, the fifth cogwheel 92 on the countershaft 18, and the sixth cogwheel 94 on the output shaft 20 of the gearbox 2. The vehicle 1 will thus begin to move off and be propelled by a first gear.

[0083] When the countershaft 18 is made to rotate by the fourth cogwheel 82 on the countershaft 18, the third cogwheel 76 on the countershaft 18 will also rotate. Thus, the countershaft 18 operates the third cogwheel 76, which in turn operates the third pinion gear 74 on the first main shaft 34. When the first main shaft 34 rotates, the first sun wheel 26 will also rotate, and thus, depending on the rotational speed of the output shaft 97 of the combustion engine 4 and thus the rotational speed of the first planetary wheel carrier 50, it will cause the first internal ring gear 22 and the first rotor 24 of the first electrical machine 14 to rotate. It is thus possible to allow the first electrical machine 14 to operate as a generator to supply power to the energy storage device 46, and/or to supply power to the second electrical machine 16. It is also possible for the second electrical machine 16 to be operated as a generator. Alternatively, the first electrical machine 14 may emit a torque injection, by way of the control device 48 controlling the first electrical machine 14 to provide a driving torque.

[0084] In order to shift from a first gear to a second gear, the locking between the second sun wheel 32 and the second planetary wheel carrier 51 must cease, which is achieved by way of the first electrical machine 14 and/or the second electrical machine 16 being controlled in such a way that torque balance prevails in the second planetary gear 12. Subsequently, the second coupling device 58 is controlled, so that it disconnects the second sun wheel 32 and the second planetary wheel carrier 51 from each other. This assumes that the second electrical machine 16 does not operate the second ring gear 28. The second gear is connected, by way of the control device 48 controlling the combustion engine 4, so that a synchronous rotational speed arises between the first planetary wheel carrier 50 and the first sun wheel 26, in order to achieve a locking between the first planetary wheel carrier 50 and the first sun wheel 26. This is achieved by way of controlling the first coupling

device 56 in such a way that the first planetary wheel carrier 50 and the first sun wheel 26 are mechanically connected with each other. Alternatively, the first coupling device 56 may be adapted as a slip brake or a multi-plate clutch which connects, in a smooth way, the first sun wheel 26 with the first planetary wheel carrier 50. By synchronizing the control of the second and first electrical machines 14 and 16, respectively, a soft and disruption-free transition from a first to a second gear may be carried out.

[0085] The first main shaft 34 now rotates, operated by the output shaft 97 of the combustion engine 4, and the first main shaft 34 now operates the third pinion gear 74. The first planetary wheel carrier 50 thus operates the third pinion gear 74 via the first sun wheel 26 and the first main shaft 34. Since the third cogwheel 76 is in engagement with the third pinion gear 74 and is connected with the countershaft 18, the third cogwheel 76 will operate the countershaft 18, which in turn operates the fifth cogwheel 92 on the countershaft 18. The fifth cogwheel 92 in turn operates the output shaft 20 of the gearbox 2 via the sixth cogwheel 94, which is arranged on the output shaft 20 of the gearbox 2. The vehicle 1 is now operated with a second gear.

[0086] When the countershaft 18 is made to rotate by the third cogwheel 76, the fourth cogwheel 82 will also rotate. Thus, the countershaft 18 operates the fourth cogwheel 82, which in turn operates the fourth pinion gear 80 on the second main shaft 36. When the second main shaft 36 rotates, the second planetary wheel carrier 51 will also rotate, and thus, depending on the rotational speed of the output shaft 97 of the combustion engine 4, and thus the rotational speed in the first planetary wheel carrier 50, it will cause the second internal ring gear 28 and the second rotor 30 of the second electrical machine 16 to rotate. It is thus possible to allow the second electrical machine 16 to operate as a generator to supply power to the energy storage device 46, and/or to supply power to the first electrical machine 14. The second electrical machine 16 may also emit a torque injection, by way of the control device 48 controlling the second electrical machine 16 to provide a propulsion torque.

[0087] In order to shift from a second gear to a third gear, the fourth cogwheel 82 on the countershaft 18 must be disconnected from the countershaft 18 with the fourth coupling element 90, so that the fourth cogwheel 82 may rotate freely in relation to the countershaft 18. Subsequently, the countershaft 18 is connected with the second cogwheel 70 on the countershaft 18 via the second coupling element 86. In order to achieve a connection of the countershaft 18 and the second cogwheel 70 on the countershaft 18, preferably the second electrical machine 16 is controlled in such a way that a synchronous rotational speed arises between the countershaft 18 and the second cogwheel 70 on the countershaft 18. A synchronous rotational speed may be achieved by way of measuring the rotational speed in the second rotor 30 in the second electrical machine 16, and measuring the rotational speed in the output shaft 20. Thus, the rotational speed in the second main shaft 36 and the rotational speed in the countershaft 18 may be determined by way of given gear ratios. The rotational speed of the respective shafts 18, 36 is controlled, and when a synchronous rotational speed has arisen between the countershaft 18 and the second cogwheel 70, the countershaft 18 and the second cogwheel 70 are connected with the assistance of the second coupling element 86.

[0088] In order to complete the shift from a second gear to a third gear, the locking between the first sun wheel 26 and the first planetary wheel carrier 50 must cease, which is achieved by way of the first and/or the second electrical machine 14, 16 being controlled in such a way that torque balance prevails in the first planetary gear 10, following which the first coupling device 56 is controlled, so that it disconnects the first sun wheel 26 and the first planetary wheel carrier 50 from each other. Subsequently, the combustion engine 4 is controlled in such a way that a synchronous rotational speed arises between the second sun wheel 32 and the second planetary wheel carrier 51, so that the second coupling device 58 may be engaged in order thus to connect the second sun wheel 32 with the second planetary wheel carrier 51, via the coupling sleeve 57. By synchronizing the control of the combustion engine 4 and of the second and first electrical machine 14 and 16, respectively, a soft and disruption-free transition from a second to a third gear may be carried out.

[0089] The third cogwheel 76 is disconnected by controlling the first electrical machine 14 in such a way that a substantially zero torque state arises between the countershaft 18 and the third cogwheel 76. When a substantially zero torque state arises, the third cogwheel 76 is disconnected from the countershaft 18 by controlling the third coupling element 88, so that it releases the third cogwheel 76 from the countershaft 18. Subsequently, the first electrical machine 14 is controlled in such a way that a synchronous rotational speed arises between the countershaft 18 and the first cogwheel 64. When a synchronous rotational speed arises, the first cogwheel 64 is connected to the countershaft 18 by way of controlling the first coupling element 84, so that it connects the first cogwheel 64 on the countershaft 18. A synchronous rotational speed may be determined, since the rotational speed of the first rotor 24 in the first electrical machine 14 is measured and the rotational speed of the output shaft 20 is measured, following which the rotational speeds of the shafts 18, 34 are controlled in such a way that a synchronous engine speed arises. Thus, the rotational speed of the first main shaft 34 and the rotational speed of the countershaft 18 may be determined by way of given gear ratios.

[0090] The second main shaft 36 now rotates with the same rotational speed as the output shaft 97 of the combustion engine 4, and the second main shaft 36 now operates the second pinion gear 68 via the second main shaft 36. Since the second cogwheel 70 is in engagement with the second pinion gear 68 and is connected with the countershaft 18, the second cogwheel 70 will operate the countershaft 18, which in turn operates the fifth cogwheel 92 on the countershaft 18. The fifth cogwheel 92 in turn operates the output shaft 20 of the gearbox 2 via the sixth cogwheel 94, which is arranged on the output shaft 20 of the gearbox 2. The vehicle 1 is now driven in a third gear.

[0091] When the countershaft 18 is made to rotate by the second cogwheel 70 on the countershaft 18, the first cogwheel 64 on the countershaft 18 will also rotate. Thus, the countershaft 18 operates the first cogwheel 64, which in turn operates the first pinion gear 62 on the first main shaft 34. When the first main shaft 34 rotates, the first sun wheel 26 will also rotate, and thus, depending on the rotational speed of the output shaft 97 of the combustion engine 4 and thus the rotational speed of the first planetary wheel carrier 50, it will cause the first internal ring gear 22 and the first rotor 24

of the first electrical machine 14 to rotate. It is thus possible to allow the first electrical machine 14 operate as a generator to supply power to the energy storage device 46, and/or to supply power to the second electrical machine 16. Alternatively, the first electrical machine 14 may emit a torque injection, by way of the control device 48 controlling the first electrical machine 14 to provide a driving torque.

[0092] In order to complete the shift from the third to the fourth gear, the locking between the second sun wheel 32 and the second planetary wheel carrier 51 must cease, which is achieved by way of the first and/or the second electrical machine 14, 16 being controlled in such a way that torque balance prevails in the second planetary gear 12, following which the second coupling device 58 is controlled in such a way that it disconnects the second sun wheel 32 and the second planetary wheel carrier 51 from each other. A fourth gear is subsequently connected by way of the control device 48 controlling the combustion engine 4, so that a synchronous rotational speed arises between the first planetary wheel carrier 50 and the first sun wheel 26, to achieve a locking between the first planetary wheel carrier 50 and the first sun wheel 26. This is achieved by way of controlling the first coupling device 56 in such a way that the first planetary wheel carrier 50 and the first sun wheel 26 are mechanically connected with each other. By synchronizing the control of the combustion engine 4 and the second and first electrical machine 14 and 16 a soft and disruption-free transition from a third to a fourth gear may be carried out.

[0093] The first main shaft 34 now rotates and is operated by the output shaft 97 of the combustion engine 4 and the first main shaft 34 now operates the first pinion gear 62. The first planetary wheel carrier 50 thus operates the first pinion gear 62 via the first sun wheel 26 and the first main shaft 34. Since the first cogwheel 64 is in engagement with the first pinion gear 62 and is connected with the countershaft 18, the first cogwheel 64 will operate the countershaft 18, which in turn operates the fifth cogwheel 92 on the countershaft 18. The fifth cogwheel 92 in turn operates the output shaft 20 of the gearbox 2 via the sixth cogwheel 94, which is arranged on the output shaft 20 of the gearbox 2. The vehicle 1 is now driven in a fourth gear.

[0094] When the countershaft 18 is made to rotate by the first cogwheel 64, the second cogwheel 70 will also rotate. Thus, the countershaft 18 operates the second cogwheel 70, which in turn operates the second pinion gear 68 on the second main shaft 36. When the second main shaft 36 rotates, the second planetary wheel carrier 51 will also rotate, and thus, depending on the rotational speed of the output shaft 97 of the combustion engine 4, and thus the rotational speed in the first planetary wheel carrier 50, it will cause the second internal ring gear 28 and the second rotor 30 of the second electrical machine 16 to rotate. It is thus possible to allow the second electrical machine 16 to operate as a generator to supply power to the energy storage device 46, and/or to supply power to the first electrical machine 14. The second electrical machine 16 may also emit a torque injection, by way of the control device 48 controlling the second electrical machine 16 to provide a propulsion torque.

[0095] In order to shift from a fourth gear to a fifth gear, the second electrical machine is activated to transfer the propulsion torque via the second gear pair 66, following which the first cogwheel 64 is disengaged from the countershaft 18, so that the fourth gear is disconnected. This is achieved by way of controlling the combustion engine 4 and

the first electrical machine 14, in such a way that the first cogwheel 64 is brought to a substantially zero torque state in relation to the countershaft 18. When a substantially zero torque state has arisen, the first coupling element 84 is disengaged, so that the first cogwheel 64 is disconnected from the countershaft 18.

[0096] Subsequently, torque balance is created in the first planetary gear 10, following which the first coupling device 56 is disconnected. Subsequently, the rotational speed of the first main shaft 34 is synchronized with the rotational speed of the output shaft 20, following which the coupling mechanism 96 is controlled in such a way that it connects the first main shaft 34 with the output shaft 20.

[0097] Subsequently, the combustion engine 4 and the first electrical machine 14 are controlled in such a way that the propulsion torque occurs via the first main shaft 34 and via the coupling mechanism 96, and further along to the output shaft 20. By reducing the torque from the second electrical machine 16, the fifth coupling element 93 may be brought to a substantially zero torque state in relation to the countershaft 18. When a substantially zero torque state has arisen, the fifth coupling element 93 is disengaged, so that the fifth cogwheel 92 of the fifth gear pair 21 is disconnected from the countershaft 18.

[0098] Subsequently, with the help of the second electrical machine 16, the rotational speed of the countershaft 18 is synchronized with the rotational speed of the third cogwheel 76, following which the third coupling element 88 is controlled in such a way that it connects the third cogwheel 76 with the countershaft 18. When this connection has been completed, the propulsion torque may be shared between the combustion engine 4, the first electrical machine 14 and the second electrical machine 16. Finally, the second planetary wheel carrier 51 is rotational speed synchronized with the second sun wheel 32, following which the second coupling device 58 connects the second planetary wheel carrier 51 and the second sun wheel 32 with each other.

[0099] The second main shaft 36 now rotates, operated by the output shaft 97 of the combustion engine 4, and the second main shaft 36 operates the second pinion gear 68. Since the second cogwheel 70 is in engagement with the second pinion gear 68 and is connected with the countershaft 18 via the second coupling element 86, the second cogwheel 70 will operate the countershaft 18, which in turn operates the third cogwheel 76 on the countershaft 18. The third cogwheel 76 in turn operates the first main shaft 34 via the third pinion gear 74, and the output shaft 20 of the gearbox 2 is thus operated via the coupling mechanism 96, which connects the first main shaft 34 and the output shaft 20 of the gearbox 2. The vehicle 1 is now driven in a fifth gear.

[0100] In order to shift from a fifth to a sixth gear, the locking between the second sun wheel 32 and the second planetary wheel carrier 51 must cease, which is achieved by way of controlling the first and/or the second electrical machine 14, 16 in such a way that torque balance prevails in the second planetary gear 12, following which the second coupling device 58 is controlled in such a way that it disconnects the second sun wheel 32 and the second planetary wheel carrier 51 from each other. A sixth gear is subsequently connected, by way of the control device 48 controlling the first and/or the second electrical machine 14, 16 in such a way that a synchronous rotational speed arises between the first planetary wheel carrier 50 and the first sun wheel 26, to achieve a locking between the first planetary

wheel carrier 50 and the first sun wheel 26. This is achieved by way of controlling the first coupling device 56 in such a way that the first planetary wheel carrier 50 and the first sun wheel 26 are mechanically connected with each other. By synchronizing the control of the combustion engine 4 and of the second and first electrical machine 14 and 16, respectively, a soft and disruption-free transition from a fifth to a sixth gear may be carried out.

[0101] The first main shaft 34 now rotates operated by the output shaft 97 of the combustion engine 4, whereat the first main shaft 34 operates the output shaft 20 of the gearbox 2 via the coupling mechanism 96, which connects the first main shaft 34 and the output shaft 20 of the gearbox 2. The vehicle 1 is now driven in a sixth gear.

[0102] In order to shift from a sixth to a seventh gear, the third cogwheel 76 on the countershaft 18 must first be disconnected from the countershaft 18 with the third coupling element 88, so that the third cogwheel 76 may rotate freely in relation to the countershaft 18. Subsequently, the countershaft 18 is connected with the first cogwheel 64 on the countershaft 18 via the first coupling element 84. When the countershaft 18 and the first cogwheel 64 on the countershaft 18 have a synchronous rotational speed, the first coupling element 84 is controlled in such a way that the first cogwheel 64 and the countershaft 18 are connected.

[0103] In order to complete the shift from a sixth gear to a seventh gear, the locking between the first sun wheel 26 and the first planetary wheel carrier 50 must cease, which is achieved by way of the first and/or the second electrical machine 14, 16 being controlled in such a way that torque balance prevails in the first planetary gear 10, following which the first coupling device 56 is controlled in such a way that it disconnects the first sun wheel 26 and the first planetary wheel carrier 50 from each other. Subsequently, the combustion engine 4 is controlled in such a way that a synchronous rotational speed arises between the second sun wheel 32 and the second planetary wheel carrier 51, so that the second coupling device 58 may be engaged in order thus to connect the second sun wheel 32 with the second planetary wheel carrier 51, via the coupling sleeve 57. By synchronizing the control of the combustion engine 4 and the second and first electrical machine 14 and 16, respectively, a soft and disruption-free transition from a sixth to a seventh gear may be carried out.

[0104] The second main shaft 36 now rotates with the same rotational speed as the output shaft 97 of the combustion engine 4, and the second main shaft 36 operates the second pinion gear 68. Since the second cogwheel 70 is in engagement with the second pinion gear 68 and is connected with the countershaft 18, the second cogwheel 70 will operate the countershaft 18, which in turn operates the fifth cogwheel 64 on the countershaft 18. The first cogwheel 64 in turn operates the first main shaft 34 via the first pinion gear 62, and the output shaft 20 of the gearbox 2 is thus operated via the coupling mechanism 96, which connects the first main shaft 34 and the output shaft 20 of the gearbox 2. The vehicle 1 is now driven in a seventh gear.

[0105] According to the embodiment above, the gearbox 2 comprises pinion gears 62, 68, 74, 80 and cogwheels 64, 70, 76, 82 arranged on the main shafts 34, 36 and the countershaft 18, respectively, to transfer rotational speed and torque. However, it is possible to use another type of transmission, such as chain and belt drives, to transfer rotational speed and torque in the gearbox 2.

[0106] The transmission device 19 has four gear pairs 60, 66, 72, 78 according to the example embodiment. However, the transmission device 19 may comprise any number of gear pairs.

[0107] It is also possible to carry out two-step shifts starting from the first gear, and further to the third gear. From the third gear a shift is then carried out to the fourth gear, and further to the fifth gear. Finally, it is possible to carry out a two-step shift from the fifth to the seventh gear. Below is a description of a shift from the first to the seventh gear, comprising a two-step shift from the first to the third gear, and a two-step shift from the fifth to the seventh gear. Such a shifting process need not be carried out in a sequence, but it is possible to shift from, for example, the fifth to the seventh gear during operation, independently of the gear steps that have been completed previously. It is also possible to carry out two-step shifts in the form of down-shifts from the seventh gear to the fifth gear, and from the third gear to the first gear.

[0108] To begin with, the first gear is engaged by way of engaging gears in the gearbox 2, corresponding to the at least one gear pair G1, 60, 72, which is connected with the first planetary gear 10, and the gear pair G2, 66, 78, which is connected with the second planetary gear 12 and the output shaft 20.

[0109] With the second coupling device 58, the second sun wheel 32, arranged in the second planetary gear 12, and the second planetary wheel carrier 51 are connected with each other. At least one gear pair G3, 21, which is connected with the countershaft 18 and the output shaft 20, is connected to the countershaft 18 via the fifth coupling element 93, in order to transfer torque to the output shaft 20. The vehicle 1 is now driven with the first gear engaged.

[0110] In order to carry out a two-step shift to the third gear, the first electrical machine 14 is activated in such a way that the first electrical machine 14 generates a propulsion torque on the output shaft 20 via the at least one gear pair G1, 60, 72, which is connected with the first planetary gear 10 and the output shaft 20, and via the at least one gear pair G3, 21, which is connected with the countershaft 18 and the output shaft 20.

[0111] Subsequently, the at least one gear pair G2, 66, 78, which is connected with the second planetary gear 12 and the output shaft 20, is disconnected from the countershaft 18 which gear pair was previously connected, by controlling the second electrical machine 16 and the combustion engine 4, connected with the first planetary gear 10, in such a way that a substantially zero torque state is achieved between the at least one gear pair G2, 66, 78, which is connected on the countershaft 18 and which is connected with the second planetary gear 12 and the output shaft 20, and the countershaft 18;

[0112] In the next step, the at least one gear pair G2, 66, 78, which is connected with the second planetary gear 12 and the output shaft 20 which gear pair was not previously connected to the countershaft 18, is connected by controlling the combustion engine 4 in such a way that a synchronous rotational speed is achieved between the at least one gear pair G2, 66, 78, which is connected with the second planetary gear 12 and the output shaft 20 which gear pair was not previously connected, and the countershaft 18.

[0113] Finally, the combustion engine 4 and/or the second electrical machine 16 is activated, so that the combustion engine 4 and/or the second electrical machine 16 generates

a propulsion torque on the output shaft 20, via the at least one gear pair G2, 66, 78, which is connected with the second planetary gear 12 and the output shaft 20, and which is now connected to the countershaft (18). The vehicle 1 is now driven with the third gear engaged.

[0114] A two-step shift in a sequence from the third gear to the fifth gear is not feasible, and instead a shift is carried out from the third gear to the fourth gear, which is described above, and subsequently a shift from the fourth to the fifth gear is carried out, which is also described above.

[0115] In order to carry out a two-step shift from the fifth gear to the seventh gear, gears in the gearbox corresponding to the at least one gear pair G1, 60, 72, which is connected with the first planetary gear 10, and the at least one gear pair G2, 66, 78, which is connected with the second planetary gear 12 and the output shaft 20 are engaged in the gearbox 2. The coupling mechanism 96, which is arranged between the first planetary gear 10 and the output shaft 20, has been connected, by controlling the combustion engine 4, in such a way that a synchronous rotational speed has been achieved between the first planetary gear 10 and the output shaft 20.

[0116] Subsequently, the first electrical machine 14 is activated, so that the first electrical machine 14 generates a propulsion torque on the output shaft 20 via the coupling mechanism 96, following which the at least one gear pair G1, 60, 72, which is connected with the first planetary gear 10 and the output shaft 20, is disconnected from the countershaft 18, by way of controlling the second electrical machine 16 and the combustion engine 4, connected with the first planetary gear 10, in such a way that a substantially zero torque state is achieved between the at least one gear pair G1, 60, 72, which is connected on the countershaft 18 and which is connected with the first planetary gear 10 and the output shaft 20, and the countershaft 18. Subsequently, the at least one gear pair G1, 60, 72, which is connected with the first planetary gear 10 and the output shaft 20 which gear pair was not previously connected, is connected with the countershaft 18, by controlling the combustion engine 4 in such a way that a synchronous engine speed is achieved between the at least one gear pair G1, 60, 72, which is connected with the first planetary gear 10 and the output shaft 20, and the countershaft 18. Finally, the second electrical machine 16 and the combustion engine 4, connected with the first planetary gear 10, are controlled to generate a propulsion torque on the output shaft 20. The vehicle 1 is now driven with the seventh gear engaged.

[0117] It is also possible to carry out two-step shifts in the form of down-shifts from the seventh gear to the fifth gear, and from the third gear to the first gear. This is carried out in a similar manner as an up-shift, but with a corresponding sequence with reversed gear pairs.

[0118] FIG. 4 shows a flow chart, relating to a method to control a hybrid powertrain 3, in order to achieve shifting without any torque interruption, comprising a combustion engine 4; a gearbox 2 with an input shaft 8 and an output shaft 20, which combustion engine is connected to the input shaft 8; a first planetary gear 10, which is connected to the input shaft 8; a second planetary gear 12, connected to the first planetary gear 10; a first electrical machine 14, connected to the first planetary gear 10; a second electrical machine 16, connected to the second planetary gear 12; at least one gear pair G1, 60, 72, connected with the first planetary gear 10 and the output shaft 20; and at least one

gear pair G2, 66, 78, connected with the second planetary gear 12 and the output shaft 20.

[0119] The method according to the invention comprises the steps:

[0120] a) engaging gears in the gearbox 2, corresponding to the at least one gear pair G1, 60, 72, which is connected with the first planetary gear 10, and the at least one gear pair G2, 66, 78, which is connected with the second planetary gear 12 and the output shaft 20; and

[0121] b) connecting two rotatable components 28, 32, 51 in the second planetary gear 12 with a second coupling device 58.

[0122] Preferably, after step a) and before step b), in step c) at least one gear pair G3, 21, which is connected with the countershaft 18 and the output shaft 20, is connected.

[0123] Preferably, the at least one gear pair G3, 21, connected with a countershaft 18 and the output shaft 20, comprises a fifth and sixth cogwheel 92; 94 in engagement with each other, which fifth cogwheel 92 is arranged so that it may be connected with and disconnected from the countershaft 18 with a fifth coupling element 93, whereat the fifth cogwheel 92 is connected to the countershaft 18 in step c).

[0124] Preferably, step b) comprises control of the combustion engine 4, in such a way that a synchronous rotational speed is achieved between the two rotatable components 28, 32, 51 in the second planetary gear 12, following which the first coupling device 58 is shifted, and locks the two rotatable components 28, 32, 51 of the second planetary gear 12 with each other.

[0125] Preferably, the at least one gear pair G1, 60, 72, which is connected with the first planetary gear 10 and the output shaft 20, comprises a first pinion gear 62 and a first cogwheel 64 in engagement with each other, which first pinion gear 62 is fixedly connected with the first planetary gear 10, and which first cogwheel 64 is arranged so that it may be connected with or disconnected from a countershaft 18;

[0126] a third pinion gear 74 and a third cogwheel 76 engaged with each other, which third pinion gear 74 is fixedly arranged with the first planetary gear 10, and which third cogwheel 76 is arranged so that it may be connected with or disconnected from the countershaft 18, wherein in step a) the first or the third cogwheel 64, 76 is connected to the countershaft 18.

[0127] Preferably, at least one gear pair G2, 66, 78, which is connected with the second planetary gear 12 and the output shaft 20, comprises a second pinion gear 68 and a second cogwheel 70 in engagement with each other, which second pinion gear 68 is fixedly arranged with the second planetary gear 12, and which second cogwheel 70 is arranged so that it may be connected with or disconnected from a countershaft 18;

[0128] and also comprises a fourth pinion gear 80 and a fourth cogwheel 82 engaged with each other, which fourth pinion gear 80 is fixedly arranged with the second planetary gear 12, and which fourth cogwheel 82 is arranged so that it may be connected with or disconnected from the countershaft 18, wherein after step a), in step d) the second or the fourth cogwheel 70, 82 is connected to the countershaft 18.

[0129] The method also comprises the following steps after step b):

[0130] e) activating the first electrical machine 14, so that the first electrical machine 14 generates a propul-

sion torque on the output shaft 20 via the at least one gear pair G1, 60, 72, which is connected with the first planetary gear 10 and the output shaft 20, and via the at least one gear pair G3, 21, which is connected with the countershaft 18 and the output shaft 20;

[0131] f) disconnecting the at least one gear pair G2, 66, 78, which is connected with the second planetary gear 10 and the output shaft 20, from the countershaft 18 which gear pair was connected in step d), by controlling the second electrical machine 16 and the combustion engine 4, connected with the first planetary gear 10, in such a way that a substantially zero torque state is achieved between the at least one gear pair G2, 66, 78, which is connected on the countershaft 18 and which is connected with the second planetary gear 12 and the output shaft 20, and the countershaft 18;

[0132] g) connecting the at least one gear pair G2, 66, 78, which is connected with the second planetary gear 12 and the output shaft 20 which gear pair was not connected in step d), to the countershaft 18, by controlling the combustion engine 4 in such a way that a synchronous engine speed is achieved between the at least one gear pair G2, 66, 78, which is connected with the second planetary gear 12 and the output shaft 20 which was not connected in step d), and the countershaft 18; and

[0133] h) activating the combustion engine 4 and/or the second electrical machine 16, so that the combustion engine 4 and/or the second electrical machine 16 generates a propulsion torque on the output shaft 20, via the at least one gear pair G2, 66, 78, which is connected with the second planetary gear 12 and the output shaft 20, and which was not connected to the countershaft 18) in step d).

[0134] The method also comprises the following steps after step h):

[0135] engaging gears corresponding to the at least one gear pair G1, 60, 72, which is connected with the first planetary gear 10 in the gearbox 2, and the at least one gear pair G2, 66, 78, which is connected with the second planetary gear 12 and the output shaft 20;

[0136] locking a coupling mechanism 96, which is arranged between the first planetary gear 10 and the output shaft 20, by controlling the combustion engine 4, in such a way that a synchronous rotational speed is achieved between the first planetary gear 10 and the output shaft 20;

[0137] activating the first electrical machine 14, so that the first electrical machine 14 generates a propulsion torque on the output shaft 20 via the coupling mechanism 96;

[0138] disconnecting the at least one gear pair G1, 60, 72, which is connected with the first planetary gear 10 and the output shaft 20, from the countershaft 18 which gear pair was connected in step i), by controlling the second electrical machine 16 and the combustion engine 4, connected with the first planetary gear 10, in such a way that a substantially zero torque state is achieved between the at least one gear pair G1, 60, 72, which is connected on the countershaft 18 and which is connected with the first planetary gear 10 and the output shaft 20, and the countershaft 18;

[0139] connecting the at least one gear pair G1, 60, 72, which is connected with the first planetary gear 10 and

the output shaft 20 which gear pair was not connected in step i), with the countershaft 18, by controlling the combustion engine 4, in such a way that a synchronous rotational speed is achieved between the at least one gear pair G1, 60, 72, which is connected with the first planetary gear 10 and the output shaft 20 which was not connected in step i), and the countershaft 18; and

[0140] controlling the second electrical machine 16 and the combustion engine 4, connected with the first planetary gear 10, to generate a propulsion torque on the output shaft 20.

[0141] Preferably the combustion engine 4 is connected with a first planetary wheel carrier 50, which is connected with a second sun wheel 32 arranged in the second planetary gear 12.

[0142] Preferably, the two rotatable components 28, 32, 51 of the second planetary gear 12 comprise a second sun wheel 32 and a second planetary wheel carrier 51.

[0143] According to the invention, a computer program P is provided, stored in the control device 48 and/or the computer 53, which may comprise procedures to control the hybrid powertrain 3 according to the present invention.

[0144] The program P may be stored in an executable manner, or in a compressed manner, in a memory M and/or a read/write memory R.

[0145] The invention also relates to a computer program product, comprising program code stored in a medium readable by a computer, in order to perform the method steps specified above, when said program code is executed in the control device 48, or in another computer 53 connected to the control device 48. Said program code may be stored in a non-volatile manner on said medium readable by a computer 53.

[0146] The components and features specified above may, within the framework of the invention, be combined between different embodiments specified.

1. A method to control a hybrid powertrain, comprising a combustion engine; a gearbox with an input shaft and an output shaft, which combustion engine is connected to the input shaft; a first planetary gear, which is connected to the input shaft; a second planetary gear, connected to the first planetary gear; a first electrical machine, connected to the first planetary gear; a second electrical machine, connected to the second planetary gear; at least one gear pair, connected with the first planetary gear and the output shaft; and at least one gear pair, connected with the second planetary gear and the output shaft, said method comprising the steps:

- a) engaging gears in the gearbox corresponding to the at least one gear pair, which is connected with the first planetary gear, and the at least one gear pair, which is connected with the second planetary gear and the output shaft; and
- b) connecting two rotatable components in the second planetary gear with a second coupling device.

2. A method according to claim 1, further comprising, after step a) and before step b), in step c) at least one gear pair is connected with the countershaft and the output shaft.

3. A method according to claim 2, wherein the at least one gear pair connected with a countershaft and the output shaft comprises a fifth and sixth cogwheel in engagement with each other, which fifth cogwheel is arranged so that it may be connected with and disconnected from the countershaft with a fifth coupling element, wherein the fifth cogwheel is connected to the countershaft in step c).

4. A method according to claim 1, wherein step b) comprises controlling the combustion engine in such a way that a synchronous rotational speed is achieved between the two rotatable components of the second planetary gear, following which the second coupling device is shifted, and locks the two rotatable components in the second planetary gear with each other.

5. A method according to claim 1, wherein the at least one gear pair, which is connected with the first planetary gear and the output shaft, comprises a first pinion gear and a first cogwheel in engagement with each other, which first pinion gear is fixedly connected with the first planetary gear and which first cogwheel is arranged so that it may be connected with and disconnected from a countershaft;

and also comprises a third pinion gear and a third cogwheel engaged with each other, which third pinion gear is fixedly arranged with the first planetary gear and which third cogwheel is arranged so that it may be connected with or disconnected from the countershaft, wherein in step a) the first or the third cogwheel is connected to the countershaft.

6. A method according to claim 1, wherein the at least one gear pair, which is connected with the second planetary gear and the output shaft, comprises a second pinion gear and a second cogwheel in engagement with each other, which second pinion gear is fixedly arranged with the second planetary gear and which second cogwheel is arranged so that it may be connected with and disconnected from a countershaft;

comprises a fourth pinion gear and a fourth cogwheel engaged with each other, which fourth pinion gear is fixedly arranged with the second planetary gear and which fourth cogwheel is arranged so that it may be connected with or disconnected from the countershaft, wherein in step a) and before step b), in step d) the second or the fourth cogwheel is connected to the countershaft.

7. A method according to claim 2, further comprising, after step e), the following steps are performed:

e) activating the first electrical machine, so that the first electrical machine generates a propulsion torque on the output shaft, via the at least one gear pair, which is connected with the first planetary gear and the output shaft, and via the at least one gear pair, which is connected with the countershaft and the output shaft;

f) disconnecting the at least one gear pair, which is connected with the second planetary gear and the output shaft, from the countershaft which gear pair was connected in step d), by controlling the second electrical machine and the combustion engine, connected with the first planetary gear, in such a way that a substantially zero torque state is achieved between the at least one gear pair, which is connected on the countershaft and which is connected with the second planetary gear and the output shaft, and the countershaft;

g) connecting the at least one gear pair, which is connected with the second planetary gear and the output shaft which gear pair was not connected in step d), to the countershaft, by controlling the combustion engine in such a way that a synchronous engine speed is achieved between the at least one gear pair, which is connected with the second planetary gear and the output shaft which was not connected in step d), and the countershaft; and

h) activating the combustion engine and/or the second electrical machine, so that the combustion engine and/or the second electrical machine generates a propulsion torque on the output shaft, via the at least one gear pair, which is connected with the second planetary gear and the output shaft, and which gear pair was not connected to the countershaft in step d).

8. A method according to claim 2, further comprising the additional steps:

- i) engaging gears corresponding to the at least one gear pair, which is connected with the first planetary gear in the gearbox, and the at least one gear pair, which is connected with the second planetary gear and the output shaft;
- j) locking a coupling mechanism, which is arranged between the first planetary gear and the output shaft, by controlling the combustion engine, in such a way that a synchronous rotational speed is achieved between the first planetary gear and the output shaft;
- k) activating the first electrical machine, so that the first electrical machine generates a propulsion torque on the output shaft via the coupling mechanism;
- l) disconnecting the at least one gear pair, which is connected with the first planetary gear and the output shaft, from the countershaft which gear pair was connected in step i), by controlling the second electrical machine and a combustion engine, connected with the first planetary gear, in such a way that a substantially zero torque state is achieved between the at least one gear pair, which is connected on the countershaft and which is connected with the first planetary gear and the output shaft, and the countershaft;
- m) connecting the at least one gear pair, which is connected with the first planetary gear and the output shaft which gear pair was not connected in step i), with the countershaft, by controlling the combustion engine, in such a way that a synchronous rotational speed is achieved between the at least one gear pair, which is connected with the first planetary gear and the output shaft which gear pair was not connected in step i), and the countershaft; and
- n) controlling the second electrical machine and the combustion engine, connected with the first planetary gear, to generate a propulsion torque on the output shaft.

9. A method according to claim 1, wherein the combustion engine is connected with the first planetary wheel carrier in the first planetary gear, which is connected with a second sun wheel, arranged in the second planetary gear.

10. A method according to claim 1, wherein in step b) the two rotatable components in the second planetary gear comprise a second sun wheel and a second planetary wheel carrier.

11. A vehicle with a hybrid powertrain, said hybrid powertrain comprising:

a combustion engine;

a gearbox with an input shaft and an output shaft, which combustion engine is connected to the input shaft;

a first planetary gear, which is connected to the input shaft;

a second planetary gear, connected to the first planetary gear;

a first electrical machine, connected to the first planetary gear;

a second electrical machine, connected to the second planetary gear;

at least one gear pair, connected with the first planetary gear and the output shaft;

at least one gear pair, connected with the second planetary gear and the output shaft; and

an electric control device configured to:

- a) engage gears in the gearbox corresponding to the at least one gear pair, which is connected with the first planetary gear, and the at least one gear pair, which is connected with the second planetary gear and the output shaft; and
- b) connect two rotatable components in the second planetary gear with a second coupling device.

12. (canceled)

13. A computer program product comprising computer program code stored on a non-transitory computer readable medium readable by a computer, said computer program product used to control a hybrid powertrain comprising a combustion engine; a gearbox with an input shaft and an output shaft, which combustion engine is connected to the input shaft; a first planetary gear, which is connected to the input shaft; a second planetary gear, connected to the first planetary gear; a first electrical machine, connected to the first planetary gear; a second electrical machine, connected to the second planetary gear; at least one gear pair, connected with the first planetary gear and the output shaft; and at least one gear pair, connected with the second planetary gear and the output shaft,

said computer program code comprising computer instructions to cause one or more computer processors to perform the operations of:

- a) engaging gears in the gearbox corresponding to the at least one gear pair, which is connected with the first planetary gear, and the at least one gear pair, which is connected with the second planetary gear and the output shaft; and
- b) connecting two rotatable components in the second planetary gear with a second coupling device.
