(57) **ABSTRACT**

Solid-state transducers ("SSTs") and vertical high voltage SSTs having buried contacts are disclosed herein. An SST die in accordance with a particular embodiment can include a transducer structure having a first semiconductor material at a first side of the transducer structure, and a second semiconductor material at a second side of the transducer structure. The SST can further include a plurality of first contacts at the first side and electrically coupled to the first semiconductor material, and a plurality of second contacts extending from the first side to the second semiconductor material and electrically coupled to the second semiconductor material. An interconnect can be formed between at least one first contact and one second contact. The interconnects can be covered with a plurality of package materials.

No. 13/708,526 filed Dec. 7, 2012, now U.S. Pat. No. 8,963,121, each of which is incorporated herein by reference in its entirety.

TECHNICAL FIELD

The present technology is related to high voltage solid-state transducers and methods of manufacturing solid-state transducers and high voltage solid-state transducer dies. In particular, the present technology relates to vertical high voltage solid-state transducers having buried contacts and associated systems and methods.

BACKGROUND

Solid state lighting ("SSL") devices are designed to use light emitting diodes ("LEDs"), organic light emitting diodes ("OLEDs"), and/or polymer light emitting diodes ("PLEDs") as sources of illumination, rather than electrical filaments, plasma, or gas. Solid-state devices, such as LEDs, convert electrical energy to light by applying a bias across oppositely doped materials to generate light from an intervening active region of semiconductor material. SSL devices are incorporated into a wide variety of products and applications including common consumer electronic devices. For example, mobile phones, personal digital assistants ("PDAs"), digital cameras, MP3 players, and other portable electronic devices utilize SSL devices for backlighting. Additionally, SSL devices are also used for traffic lighting, signage, indoor lighting, outdoor lighting, and other types of general illumination.

Microelectronic device manufactures are developing more sophisticated devices in smaller sizes while requiring higher light output with better performances. To meet current design criteria, LEDs are fabricated with decreasing footprints, slimmer profiles and are subsequently serially coupled in high voltage arrays. In certain embodiments, the individual SSL dies may include more than one LED junction coupled in series.

FIG. **1**A is a cross-sectional view of a conventional high voltage SSL device **10***a* shown with two junctions in series in a lateral configuration. As shown in FIG. **1**A, the high voltage SSL device **10***a* includes a substrate **20** carrying a plurality of LED structures **11** (identified individually as first and second LED structures **11***a*, **11***b*) that are electrically isolated from one another by an insulating material **12**. Each LED structure **11***a*, **11***b* has an active region **14**, e.g., containing gallium nitride/indium gallium nitride (GaN/InGaN) multiple quantum wells ("MQWs"), positioned between P-type GaN **15** and N-type GaN **16** doped materials. The high voltage SSL device **10***a* also includes a first contact **17** on the P-type GaN **15** and a second contact **19** on the N-type GaN **16** in a lateral configuration. The individual SSL structures **11***a*, **11***b* are separated by a notch **22** through which a portion of the N-type GaN **16** is exposed. An interconnect **24** electrically connects the two adjacent SSL structures **11***a*, **11***b* through the notch **22**. In operation, electrical power is provided to the SSL device **10** via the contacts **17**, **19**, causing the active region **14** to emit light.

FIG. **1**B is a cross-sectional view of another conventional LED device **10***b* in which the first and second contacts **17** and **19** are opposite each other, e.g., in a vertical rather than lateral configuration. During formation of the LED device **10***b*, a growth substrate (not shown), similar to the substrate **20** shown in FIG. **1**A, initially carries an N-type GaN **15**, an active region **14** and a P-type GaN **16**. The first contact **17** is disposed on the P-type GaN **16**, and a carrier **21** is attached to the first contact **17**. The substrate is removed, allowing the second contact **19** to be disposed on the N-type GaN **15**. The structure is then inverted to produce the orientation shown in FIG. **1**B. In the LED device **10***b*, the first contact **17** typically includes a reflective and conductive material (e.g., silver or aluminum) to direct light toward the N-type GaN **15**. A converter material **23** and an encapsulant **25** can then be positioned over one another on the LED structure **11**. In operation, the LED structure **11** can emit a first emission (e.g., blue light) that stimulates the converter material **23** (e.g., phosphor) to emit a second emission (e.g., yellow light). The combination of the first and second emissions can generate a desired color of light (e.g., white light).

The vertical LED device **10***b* typically has higher efficiency than lateral LED device configurations. Higher efficiency can be the result of enhanced current spreading, light extraction and thermal properties, for example. However, despite improved thermal properties, the LED device **10***b* still produces a significant amount of heat that can cause delamination between various structures or regions and/or cause other damage to the packaged device. Additionally, as shown in FIG. **1**B, the vertical LED device **10***b* requires access to both sides of the die to form electrical connections with the first and second contacts **17** and **19**, and typically includes at least one wire bond coupled to the second contact **19**, which can increase a device footprint and complexity of fabrication. Some of the conventional LED die processing steps have been restricted to the package level (e.g., after singulation at a die level (FIG. **1**B)) to achieve high performance and prevent damage to the devices during processing steps. Such package-level processing steps increase demands on manufacturing resources such as time and costs as well as can have other undesirable results such as surface roughening of the package. Accordingly, there remains a need for vertical LEDs, vertical high voltage LED dies and other solid-state devices that facilitate packaging and have improved performance and reliability.

BRIEF DESCRIPTION OF THE DRAWINGS

Many aspects of the present disclosure can be better understood with reference to the following drawings. The components in the drawings are not necessarily to scale. Instead, emphasis is placed on illustrating clearly the principles of the present disclosure. Moreover, in the drawings, like reference numerals designate corresponding parts throughout the several views.

FIGS. **1**A and **1**B are schematic cross-sectional diagrams of LED devices configured in accordance with the prior art.

FIGS. **2A-2L** are schematic plan and cross-sectional views illustrating portions of a process for forming solid-state transducers in accordance with embodiments of the present technology.

FIGS. **3A** and **3B** are cross-sectional views illustrating further portions of a process for forming solid-state transducers in accordance with further embodiments of the present technology.

FIGS. **4A-4C** are schematic plan views illustrating portions of a process for forming a wafer level assembly having a plurality of solid-state transducers configured in accordance with another embodiment of the present technology.

DETAILED DESCRIPTION

Specific details of several embodiments of solid-state transducers ("SSTs") and associated systems and methods are described below. The term "SST" generally refers to solid-state devices that include a semiconductor material as the active medium to convert electrical energy into electromagnetic radiation in the visible, ultraviolet, infrared, and/or other spectra. For example, SSTs include solid-state light emitters (e.g., LEDs, laser diodes, etc.) and/or other sources of emission other than electrical filaments, plasmas, or gases. SSTs can alternately include solid-state devices that convert electromagnetic radiation into electricity. Additionally, depending upon the context in which it is used, the term "substrate" can refer to a wafer-level substrate or to a singulated device-level substrate. A person skilled in the relevant art will also understand that the technology may have additional embodiments, and that the technology may be practiced without several of the details of the embodiments described below with reference to FIGS. **2A-4C**.

FIGS. **2A-4C** are schematic plan and cross-sectional views illustrating a process for forming SSTs in accordance with an embodiment of the present technology. FIGS. **2A-2L** illustrate various portions of the process showing a single SST die **200** for clarity; however, it is understood that the illustrated steps can be implemented at the wafer-level for producing a plurality of SST dies **200** concurrently using the process steps described herein. For example, FIGS. **2A** and **2B** illustrate an SST die **200** at a stage of the process after a transducer structure **202** has been formed on a growth substrate **220**. As shown in FIG. **2B**, the SST die **200** has a first side **201*a*** and a second side **201*b*** facing away from the first side **201*a***. Referring to FIGS. **2A** and **2B** together, the SST die **200** can include a plurality of features that separate the transducer structure **202** into a plurality of junctions **203** (identified individually as junctions **203*a*-203*i***). For example, trenches **208** that extend from the first side **201*a*** of the SST die **200** through the transducer structure **202** to the substrate **220** can be formed to separate and electrically isolate the individual junctions **203** from adjacent or other junctions **203** on the SST die **200**.

The transducer structure **202** can include a first semiconductor material **210** at the first side **201*a***, a second semiconductor material **212** at the second side **201*b***, and an active region **214** located between the first and second semiconductor materials **210**, **212**. In other embodiments, the transducer structure **202** can also include silicon nitride, aluminum nitride (AlN), and/or other suitable intermediate materials.

The first and second semiconductor materials **210** and **212** can be doped semiconductor materials. In one embodiment, the first semiconductor material **210** can be a P-type semiconductor material (e.g., P—GaN), and the second semiconductor material **212** can be an N-type semiconductor material (e.g., N—GaN). In other embodiments, the first and second semiconductor materials **210** and **212** may be reversed. In further embodiments, the first and second semiconductor materials **210** and **212** can individually include at least one of gallium arsenide (GaAs), aluminum gallium arsenide (AlGaAs), gallium arsenide phosphide (GaAsP), gallium(III) phosphide (GaP), zinc selenide (ZnSe), boron nitride (BN), aluminum gallium nitride (AlGaN), and/or other suitable semiconductor materials.

The active region **214** between the first and second semiconductor materials **210** and **212** can include a single quantum well ("SQW"), MQWs, and/or a single grain semiconductor material (e.g., InGaN). In one embodiment, a single grain semiconductor material, such as InGaN can have a thickness greater than about 10 nanometers and up to about 500 nanometers. In certain embodiments, the active region **214** can include an InGaN SQW, GaN/InGaN MQWs, and/or an InGaN bulk material. In other embodiments, the active region **214** can include aluminum gallium indium phosphide (AlGaInP), aluminum gallium indium nitride (AlGaInN), and/or other suitable materials or configurations.

In certain embodiments, at least one of the first semiconductor material **210**, the active region **214**, and the second semiconductor material **212** can be formed on the growth substrate **220** via metal organic chemical vapor deposition ("MOCVD"), molecular beam epitaxy ("MBE"), liquid phase epitaxy ("LPE"), and/or hydride vapor phase epitaxy ("HVPE"). In other embodiments, at least a portion of the transducer structure **202** may be formed using other suitable epitaxial growth techniques.

As shown in FIGS. **2A** and **2B**, a first contact **204** can be formed on the first semiconductor material **210**. In some embodiments, the first contact **204** can extend over a large portion of the underlying first semiconductor material **210**. In other embodiments, the first contact **204** can be formed over a smaller portion of the first semiconductor material **210**. In certain arrangements, the first contact **204** can be a mirror and/or made from a reflective contact material, including nickel (Ni), silver (Ag), copper (Cu), aluminum (Al), tungsten (W), and/or other reflective materials. As illustrated in FIGS. **2A** and **2B**, the first contact **204** can be a continuous overlay of contact material formed over the first semiconductor material **210**; however, in other embodiments, the SST die **200** can include separate reflective elements positioned at the first side **201*a*** and overlaying portions of the first semiconductor material **210**. During subsequent processing stages, the transducer structure **202** may be inverted such that the reflective first contact **204** can redirect emissions (e.g., light) through the active region **214** and toward the second side **201*b*** of the SST die **200** (FIG. **2B**). In other embodiments, the first contact **204** can be made from non-reflective materials and/or the SST die **200** may not include reflective elements. The first contact **204** can be formed using chemical vapor deposition ("CVD"), physical vapor deposition ("PVD"), atomic layer deposition ("ALD"), spin coating, patterning, and/or other suitable techniques known in the art.

A second contact **206** can include a plurality of buried contact elements **215** that extend from the first side **201*a*** of the SST die **200** to or into the second semiconductor material **212**. Referring to FIG. **2B**, the buried contact elements **215** can be formed by etching or otherwise forming a plurality of channels or openings **219** in the transducer structure **202** that extends from the first side **201*a*** of the transducer structure **202** (e.g., the first contact **204** or the first semiconductor material **210**) to or into the second semiconductor material

212. In one embodiment, the openings **219** can be formed before the first contact **204** is formed on the first semiconductor material **210** and can extend to or into a portion of the second semiconductor material **212** (as shown in FIG. **2**B). In another embodiment, the openings **219** may be formed after the first contact material **204** is formed at the first side **201***a* of the SST die **200**. The etched sidewalls of the openings **219** can be coated with a dielectric material **218** to electrically insulate a second contact material **216** along a path extending through the first contact **204**, the first semiconductor material **210**, and the active region **214**. The dielectric material **218** can include silicon dioxide (SiO_2), silicon nitride (SiN), and/or other suitable dielectric materials and can be deposited in the openings **219** via CVD, PVD, ALD, patterning, and/or other suitable techniques known in the semiconductor fabrication arts.

In a next process step, the buried contact elements **215** can be formed by disposing the second contact material **216** in the insulated openings **219** to electrically connect with exposed portions of the second semiconductor material **212** in the openings **219**. The second contact material **216** can include titanium (Ti), aluminum (Al), nickel (Ni), silver (Ag), and/or other suitable conductive materials. The second contact material **216** can be deposited using CVD, PVD, ALD, patterning, and/or other known suitable techniques. Accordingly, as shown in FIGS. **2**A and **2**B, both the first and second contacts **204** and **206** are electrically accessible from the first side **201***a* of the SST die **200**.

FIGS. **2**C and **2**D illustrate a stage in the process after a dielectric material **222** (e.g., a passivation material) has been formed over the first contact **204**. Among other functions, the dielectric material **222** is used to protect the underlying transducer structure **202** (with certain features shown in broken lines in FIG. **2**C for clarity) from the environment and to prevent shorting the first and second contacts **204**, **206** to each other. The dielectric material **222** can be the same as or different from the dielectric material **218** in the openings **219**. For example, the dielectric material **222** can include silicon nitride (SiN), silicon dioxide (SiO_2), polyimide, and/or other suitable insulative materials. As shown in FIG. **2**C, the dielectric material **222** can include apertures **224** that expose portions of the first contact **204**. In the illustrated embodiment, the dielectric material **222** includes a rectangular aperture **224** associated with each of the individual junctions **203***a*-**203***i*. In other embodiments, however, the dielectric material **222** can include more or fewer apertures **224** and/or the apertures **224** can have different shapes (e.g., square, circular, irregular, etc.). The dielectric material **222** can be formed using CVD, PVD, patterning, spin coating, and/or other suitable formation methods. The apertures **224** can be formed by selectively depositing or selectively removing portions of the dielectric material **222**. In the illustrated embodiment, the dielectric material **222** is positioned to space the exposed first and second contacts **204** and **206** laterally apart from one another, and therefore reduce the likelihood of shorting the contacts to each other during subsequent processing.

As shown in FIGS. **2**C and **2**D, the dielectric material **222** does not cover the buried contact elements **215**. In a particular embodiment, interconnects **225** can electrically couple the second contact **206** on a junction (e.g., junction **203***d*) to the first contact **204** via the aperture **224** on an adjacent junction (e.g., junction **203***e*) such that the junctions (e.g., junctions **203***d* and **203***e*) are coupled in series. Interconnects **225** can be formed by depositing interconnect lines **226** over the dielectric material **222** between the buried contact elements **215** and the first contact **204** exposed

through the apertures **224**. The dielectric material **222** underlying the interconnect lines **226** electrically isolates the first contact **204** from the second contact **206**. The interconnect lines **226** can be made from a suitable electrically conductive material, including those used for the second contact material **216**, such as nickel (Ni), silver (Ag), copper (Cu), aluminum (Al), tungsten (W) and/or other suitable conductive materials, and can be formed using deposition, patterning, and/or other suitable methods known in the art.

As shown in FIG. **2**C, the SST die **200** includes a first external terminal **205** which can be positioned on the junction **203***a*. The first external terminal **205** can be an exposed portion of the first contact **204** accessible through the aperture **224** at the junction **203***a*. Generally, the first external terminal **205** is associated with a first junction (e.g., junction **203***a*) of the plurality of serially coupled junctions (e.g., junctions **203***a*-**203***i*); however, in other embodiments, the first external terminal **205** can be associated with another junction **203***b*-**203***i*. Similar to the rectangular apertures **224** associated with each of the other individual junctions **203***b*-**203***i*, the first external terminal **205** can be formed via a rectangular aperture **224** in the dielectric material **222** exposing the portion of first contact **204**. In other embodiments, the aperture **224** can have different shapes (e.g., square, circular, irregular, etc.) to expose the first contact **204** to form the first external terminal **205** on the SST die **200**.

Likewise, the SST die **200** includes a second external terminal **207** which can be positioned at the junction **203***i* and/or another junction that is generally at a terminal end of a serially coupled group of junctions **203**. The second external terminal **207** can be made from a suitable electrically conductive material, including those used for the second contact material **216**, such as nickel (Ni), silver (Ag), copper (Cu), aluminum (Al), tungsten (W) and/or other suitable conductive materials. The second external terminal **207** can be electrically coupled to the second contact **206** and/or the second semiconductor material **212** of the associated junction (e.g., junction **203***i*). For example, as illustrated in FIG. **2**C, the second external terminal **207** can be formed using deposition, patterning, and/or other suitable methods known in the art over the dielectric material **222** and electrically connected to the second contact **206** of the associated junction (e.g., junction **203***i*).

In operation, the first and second terminals **205**, **207** can be directly attached and/or otherwise externally coupled to external devices, components or power sources (e.g., AC or DC power supplies). The individual junctions **203***a*-**203***i* are configured to emit light and/or other types of electromagnetic radiation in response to an applied electrical voltage. In one example, the SST die **200** can be coupled serially or in parallel with other SST dies in an SST array to achieve high input voltage in the devices incorporating the SST dies **200**, thereby improving device performance.

Optionally, and in another embodiment, the SST die **200** can have a third contact or cross-connection contact **250** (shown in dotted lines at junction **203***c*, for example) electrically coupled to the interconnect **225** or interconnect lines **226** at one or more the intermediate junctions (e.g., junctions **203***b*-**203***h*). Cross-connection contacts **250** can be used to form cross connections with additional dies coupled in an array, such as an SST array. Cross-connection contacts and cross-connections are described in detail with respect to the solid-state transducers and high voltage SST arrays described in U.S. patent application Ser. No. 13/603,106, which is incorporated herein by reference in its entirety. Accordingly, the cross-connection contact **250** electrically

coupled to the interconnects **125** between junctions **203** (e.g., between junctions **203***c* and **203***d*) provide the accessible electrical connection within high voltage (e.g., multiple junction) SST dies **200**. As such, input voltage provided through terminals **205**, **207** may flow through the serially coupled junctions **203** and also between parallel coupled strings (not shown) of SST dies **200** to provide alternative electrical paths for improving light output and higher flux delivery. Accordingly, array assemblies (not shown) which incorporate the SST dies **200** having the cross-connection contacts **250**, have provisions to overcome junction failure, providing reduced variation in bias across individually coupled SST dies **200** in the array. Moreover, the array assemblies can remain in use even after a junction failure, providing improved chip performance and reliability, thereby reducing manufacturing costs.

In additional embodiments, the SST die **200** can include multiple cross-connection contacts **250** associated with the multiple interconnects **125** for providing additional cross-connections (not shown) between, for example, parallel-coupled SST dies **200**. In such embodiments, array assemblies (not shown) incorporating SST dies **200** having one or more cross-connection contacts **250** can be configured to include a plurality of cross-connections (not shown) electrically coupling interconnects **225** of SST dies **200** between strings of dies coupled in parallel, for example.

In one embodiment, the cross-connection contact **250** is externally accessible at the first side **201***a* of the SST die **200** and a cross-connection can be formed by wire bonding and/or direct attachment. In other embodiments, the cross-connection contact **250** can be positioned at the first side **201***a* of the SST die **200** with suitable insulating or dielectric materials intervening between the cross-connection contact **250** and the underlying first semiconductor material **210** and first contact **204**. Suitable materials for cross-connection contacts **250** can include titanium (Ti), aluminum (Al), nickel (Ni), silver (Ag), and/or other suitable conductive materials. The cross-connection contact **250** can also be formed using CVD, PVD, ALD or other suitable techniques known in the semiconductor fabrication arts.

FIGS. **2**E-**2**L illustrate stages in the process during which an additional dielectric portions and conductive material are added to the SST die **200**. Certain underlying features of the SST die **200** are shown in broken lines in FIGS. **2**E, **2**G and **2**I for purposes of illustration only. In one embodiment, an additional dielectric portion **228** can be formed of the same material as the dielectric material **222**, or can be different material. For example, the additional dielectric portion **228** can comprise silicon nitride, silicon dioxide, polyimide and/or other suitable dielectric materials. As shown in FIGS. **2**E and **2**F, the additional dielectric portion **228** (e.g., a passivation portion) can be selectively deposited (e.g., via CVD, PVD, or other suitable processes) over portions of the SST die **200** that include the first contacts **204**, the second contacts **206**, the interconnect lines **226** and the interconnects **225**. In some embodiments, the additional dielectric portion **228** can be pre-formed and positioned over the selected electrical contacts and interconnecting portions of the SST die **200**. In the illustrated embodiment, the additional dielectric portion **228** is positioned over all of the first contacts **204**, the second contacts **206**, the interconnect lines **226** and the interconnects **225**. Additionally, and as shown in FIG. **2**E, the additional dielectric portion **228** is positioned, deposited, patterned and/or otherwise configured so as not to cover the first and second external terminals **205**, **207**. In other embodiments, the SST dies **200** can include larger or smaller regions of dielectric material and/or portion **222** and **228** that cover larger or smaller portions of the first and second contacts **204** and **206** and the interconnects **225**. For example, the dielectric material and/or portion **222** and **228** can be deposited such that one or more second contacts **206** are exposed.

FIGS. **2**G and **2**H illustrate the addition of barrier material **232**, such as a barrier metal, that can be deposited over the dielectric material **222** and/or the additional dielectric portion **228** on the first side **201***a* of the SST die **200**. The barrier material **232** can include cobalt, ruthenium, tantalum, tantalum nitride, indium oxide, tungsten nitride, titanium nitride, tungsten titanium (Wti), and/or other suitable isolative conductive materials, and can be deposited using CVD, PVD, ALD, patterning, and/or other suitable techniques known in the art.

Referring next to FIGS. **2**I and **2**J, a metallic seed material **234** can be deposited over and adhered to the barrier material **232** on the first side **201***a* of the SST die **200** to provide, for example, a conductive connection between the underlying transducer structure **202** and other external components. In the illustrated embodiment, the seed material **234** covers the entire first side **201***a*. In one embodiment, the seed material **234** can include a thin and continuous overlay, or in other arrangements, a non-continuous overlay of Copper (Cu), a titanium/copper alloy, and/or other suitable conductive materials, and can be deposited by electroplating, electroless plating, or other methods. For example, the seed material **234** can be deposited using CVD, PVD, ALD, patterning, sputter-depositing and/or other suitable techniques known in the art.

Referring to FIGS. **2**G-**2**J together, the barrier material **232** prevents the diffusion of the seed material **234** (e.g., Cu seed material) from diffusing into the underlying semiconductor materials, such as the dielectric material **222**, the additional dielectric portion **228**, or the transducer structure **202**, including the first and second semiconductor materials **210**, **212** and the active region **214**, which could alter the electrical characteristics of the SST die **200**.

FIGS. **2**I and **2**J also illustrate a stage in the process in which the seed material **234** and the barrier material **232** is patterned to expose the underlying dielectric material **222** or the additional dielectric portion **228**. As shown in FIG. **2**I, the seed material **234** and barrier material **232** can be selectively removed or etched to create a dielectric path **236** on the first side **201***a* that surrounds and electrically isolates the first external terminal **205** and the second external terminal **207**. In another embodiment the barrier material **232** and/or seed material **234** can be selectively deposited over the dielectric material **222** and dielectric portion **228** while leaving those sections forming the dielectric path **236** void of barrier material **232** and/or seed material **234**, respectively.

FIGS. **2**K and **2**L illustrate a stage in the process in which a metal substrate **238** is formed over the seed material **234** on the first side **201***a* of the SST die **200**. In one embodiment, the metal substrate **238** can comprise copper (Cu), aluminum (Al), an alloy (e.g., a NiFe alloy), or other suitable material. The metal substrate can be formed by electroplating, electroless plating, or other technique know in the art. In some embodiments, the metal substrate **238** can have a thickness of approximately 100 μm; however, in other embodiments, the metal substrate **238** can have a variety of thicknesses. As shown in FIGS. **2**K and **2**L, the metal substrate **238** (e.g., thick copper substrate) can be patterned to expose the underlying dielectric material **222** or the additional dielectric portion **228** along the dielectric path **336**. In one embodiment, the metal substrate **238** can be

selectively plated such that those sections of the dielectric material **222** and the dielectric portion **228** forming the dielectric path **236** is void of the metal substrate **238**. As described, the dielectric path **236** surrounds and electrically isolates the first external terminal **205** and the second external terminal **207**. The conductive metal substrate **238** electrically and vertically coupled to the first and second external terminals **205**, **207** and surrounded by the dielectric path **236**, provides external bonding sites for direct attachment of external components without the need for additional wire bonds or bond pads.

Referring back to FIG. **2**K, the metal substrate **238** can be thermally conductive to transfer heat from the SST die **200** to an external heat sink (not shown) and provide the SST die **200** with a thermal pad **240** on the first side **201***a*. For example, the metal substrate **238** can comprise copper, aluminum or an alloy that has a coefficient of thermal expansion at least generally similar to the coefficient of thermal expansion of the SST die **200** or to that of a larger package or circuit board that the SST die **200** is associated. Accordingly, the thermal pad **240** can decrease the operating temperature of the SST die **200** by transferring heat to a board, a package, a heat sink, or another element of a device that includes the SST die **200**. Additionally, although the illustrated embodiment of FIG. **2**K includes only one thermal pad **240**, in other embodiments, the SST die **200** may include a plurality of smaller and/or separate thermal pads **240** having any of a variety of suitable sizes and shapes and located at any of a variety of suitable positions on the first side **201***a* of the SST die **200**.

The SST die **200** (FIG. **2**L) can be attached to another carrier substrate (not shown) or otherwise inverted and the metal substrate **238** can provide a support for further processing on the second side **201***b* of the SST die **200**. FIGS. **3**A-**3**B are schematic cross-sectional views of the SST die **200** of FIG. **2**L in various stages of further processing. For example, FIGS. **3**A and **3**B illustrate a step in the process where the SST die **200** has been inverted, and the growth substrate **220** has been removed (FIG. **4**B), such that the transducer structure **202** is exposed at the second side **201***b* of the SST die **200**. The growth substrate **220** can be removed by chemical-mechanical planarization (CMP), backgrinding, etching (e.g., wet etching, dry etching, etc.), chemical or mechanical lift-off, and/or other removal techniques. The process can also include roughening of the second semiconductor material **212** (not shown). Similarly, the metal substrate **138** can be ground or thinned, if desired, by backgrinding, CMP, etching, and/or other suitable methods (not shown). In further embodiments not shown, the SST die **200** can undergo additional processing to enhance or improve (e.g., optimize) optical properties, and/or other properties. For example, optical elements, such as lenses, can be added to second side **201***b* of the SST die **200**. The resulting SST die **200** includes the first external terminal **205** (shown in FIG. **2**K), a second external terminal **207**, and the thermal pad **240** (shown in FIG. **2**K) at the first side **201***a* and that can be mounted on a board, a package or another component without requiring wire bonds e.g., using a solder reflow process. Accordingly, the direct attach terminals **205**, **207** and thermal pad **240** allow the SST die **200** to be efficiently mounted to a board or other substrate or support in a single step process.

For illustrative purposes, FIGS. **2**A-**3**B show stages of a fabrication process on an individual SST die **200**. FIGS. **4**A-**4**C show portions of wafer-level assemblies having a plurality of SST dies **200**. A person skilled in the art will recognize that each stage of the processes described herein can be performed at the wafer level or at the die level. FIG. **4**A is a plan view of a portion of a wafer level assembly **400** having a first side **401***a* and including four individual SST dies **200** generally similar to that shown in FIG. **2**I. Accordingly, FIG. **4**A illustrates a stage in the process of fabrication in which the metallic seed material **234** is deposited over and adhered to the underlying barrier material **232** (shown in FIGS. **2**G, **2**H and **2**J, for example) on the first side **401***a* of the wafer level assembly **400** to provide, for example, a conductive connection between the underlying transducer structures **202** (shown in FIG. **2**J) and other external components. As shown in FIG. **4**A, the seed material **234** and the barrier material **232** (shown in FIG. **2**J) are patterned to expose the underlying dielectric material **222** or the additional dielectric portion **228** and create a plurality of dielectric paths **236**.

FIG. **4**B is a plan view of the portion of the wafer level assembly **400** at a stage in the process generally similar to that shown in FIG. **2**K. For example, FIG. **4**B illustrates a stage in the process of fabrication in which the metal substrate **238** is formed over the seed material **234** on the first side **401***a* of the wafer level assembly **400** and patterned to form the plurality of dielectric paths **236**. Each of the individual SST dies **200** includes a thermal pad **240**. As shown in FIG. **4**C, the assembly **400** can be diced along dicing lanes **402** to form singulated SST dies **200**, or in another embodiment, can be processed to form an SST array. The singulated SST dies **200** include the first external terminal **205**, the second external terminal **207** and the thermal pad **240** at the first side **201***a*, **401***a*.

From the foregoing, it will be appreciated that specific embodiments of the technology have been described herein for purposes of illustration, but that various modifications may be made without deviating from the disclosure. The SST dies **200** and the assembly **400** can include additional components, and/or different combinations of the components described herein. For example, the SST dies **200** and/or the assembly **400** can be incorporated into SST arrays having multiple dies or assemblies. Further, optical elements, such as lenses can be added to each of the individual SST dies **200**. Furthermore, the assembly **400** includes a 2×2 array of SST dies **200**, however, in other embodiments, assemblies can include different numbers of SST dies and/or have different shapes (e.g., rectangular, circular, etc.). Additionally, certain aspects of the present technology described in the context of particular embodiments may be eliminated in other embodiments. For example, the configuration of the dielectric material **222** and the dielectric portion **228** can be altered to expose or cover differing combinations of contacts, interconnects and/or other conductive lines. Additionally, while features associated with certain embodiments of the present technology have been described in the context of those embodiments, other embodiments may also exhibit such features, and not all embodiments need necessarily exhibit such features to fall within the scope of the technology. Accordingly, the disclosure and associated technology can encompass other embodiments not expressly shown or described herein.

We claim:

1. A solid-state transducer (SST) die, comprising:

a transducer structure having a first semiconductor material on a first side and a second semiconductor material on a second side, wherein the transducer structure is separated into at least first and second electrically isolated junctions;

a first contact electrically coupled to the first semiconductor material at the first junction;

a second contact electrically coupled to the second semiconductor material at the second junction, wherein the second contact extends through the first semiconductor material and is electrically isolated from the first semiconductor material;

an interconnect formed between the first contact and the second contact such that the first and second junctions are electrically connected in series; and

a third contact connected to the interconnect, the third contact configured to cross-connect to another contact on a second SST die.

2. The SST die of claim **1** wherein the second contact extends through a channel formed through the first semiconductor material.

3. The SST die of claim **2**, further comprising a light-emitting active material disposed between the first semiconductor material and the second semiconductor material, and wherein the second contact extends through the channel formed through the first semiconductor material and through the light-emitting active material.

4. The SST die of claim **2**, wherein the channel is lined with a dielectric material to electrically insulate the second contact from the first semiconductor material.

5. The SST die of claim **1**, further comprising a dielectric material between the interconnect and the first semiconductor material and a plurality of package materials covering the interconnect.

6. The SST die of claim **1** wherein the first contact and the second contact are buried, and wherein the SST die further comprises a first external terminal and a second external terminal, and wherein the first and second external terminals are configured to connect to a power source.

7. The SST die of claim **1** wherein the transducer structure is a vertical transducer structure having the first contact and second contact at the first side, and wherein the SST die is configured to directly attach to an external component.

8. The SST die of claim **1** wherein each junction comprises an individually addressable light-emitting diode (LED) die.

9. The SST die of claim **1**, further comprising a thermal pad disposed on the first side.

10. The SST die of claim **1**, further comprising a dielectric material over the first contact, the dielectric material having a plurality of openings that are aligned with the first and second contacts.

11. A light-emitting diode (LED) comprising:

a light-emitting transducer structure having a light-emitting active region positioned between a first semiconductor material and a second semiconductor material, the transducer structure separated into at least first and second electrically isolated junctions;

a first contact electrically coupled to the first semiconductor material at the first junction;

a second contact electrically coupled to the second semiconductor material at the second junction, wherein the second contact extends through the first semiconductor material and is electrically isolated from the first semiconductor material;

an interconnect formed between the first contact and the second contact such that the first and second junctions are electrically connected in series; and

a third contact connected to the interconnect, the third contact configured to cross-connect to another contact on a second LED.

12. The LED of claim **11** wherein the second contact extends through the light-emitting active region.

13. The LED of claim **12** wherein the second contact extends through a channel formed through the first semiconductor material and the light-emitting active region.

14. The LED of claim **12** wherein the channel is lined with a dielectric material to electrically insulate the second contact from the first semiconductor material.

15. The LED of claim **11**, further comprising a passivation material over the interconnect such that the interconnect is encased in the passivation material.

16. The LED of claim **11**, further comprising a plurality of package materials over the passivation material and the interconnect.

17. The LED of claim **11**, further comprising a thermal pad on the first side.

18. The LED of claim **11**, further comprising a dielectric material over the first contact, the dielectric material having a plurality of openings that are aligned with the first and second contacts.
