(57) **ABSTRACT**

A method of processing a substrate includes forming a first layer stack on a substrate, the first layer stack including conductive layers and dielectric layers that alternate in the first layer stack. An opening is formed in the first layer stack, the opening extending through each of the conductive layers in the first layer stack such that sidewalls of each of the conductive layers are exposed within the opening. A second stack of layers is formed within the opening, the second stack of layers including channel layers of semiconductor material positioned in the second stack such that each channel layer contacts exposed sidewalls of a respective conductive layer of the first layer stack. Transistor channels are from the channel layers of the second stack such that each transistor channel extends between exposed sidewalls of a respective conductive layer within the opening.

METHOD FOR DESIGNING THREE DIMENSIONAL METAL LINES FOR ENHANCED DEVICE PERFORMANCE

CROSS REFERENCE TO RELATED APPLICATIONS

[0001] The present application claims the benefit of U.S. Prov. Ser. No. 63/107768, entitled "Advanced Design of 3D Metal Lines for Enhanced 3D Device Performance", filed on Oct. 30, 2020. The entire content of the above application is incorporated by reference herein.

BACKGROUND

Field of the Invention

[0002] This disclosure relates to microelectronic devices including semiconductor devices, transistors, and integrated circuits, including methods of microfabrication.

Description of the Related Art

[0003] The background description provided herein is for the purpose of generally presenting the context of the disclosure. Work of the presently named inventors, to the extent the work is described in this background section, as well as aspects of the description that may not otherwise qualify as prior art at the time of filing, are neither expressly nor impliedly admitted as prior art against the present disclosure.

[0004] Semiconductor technologies are continually progressing to smaller feature sizes of 14 nanometers and below. The continual reduction in sizes of features, from which the foregoing elements are fabricated, places ever-greater demands on techniques used to form the features. During the manufacturing of a semiconductor device (especially on the microscopic scale), various fabrication processes are executed such as film-forming depositions, etch mask creation, patterning, material etching and removal, and doping treatments. These processes are performed repeatedly to form desired semiconductor device elements on a substrate. Historically, with microfabrication, transistors have been created in one plane, with wiring/metallization formed above the active device plane, and have thus been characterized as two-dimensional (2D) circuits or 2D fabrication. Scaling efforts have greatly increased the number of transistors per unit area in 2D circuits, yet scaling efforts are running into greater challenges as scaling enters single digit nanometer semiconductor device fabrication nodes. Semiconductor device fabricators have expressed a desire for three-dimensional (3D) semiconductor circuits in which transistors are stacked on top of each other.

[0005] Accordingly, it is one object of the present disclosure to provide methods and systems for designing three dimensional metal lines for enhanced device performance.

SUMMARY OF THE INVENTION

[0006] Aspects of the present disclosure methods and structures for designing three dimensional metal lines for enhanced device performance by combining 3D metal layers within different layers of a 3D dielectric stack to generate an enhanced 3D stack of horizontal nano sheets.

[0007] Aspect (1) includes a method of processing a substrate, the method including: forming a first layer stack on a substrate, the first layer stack including conductive layers and dielectric layers that alternate in the first layer stack; forming an opening in the first layer stack, the opening extending through each of the conductive layers in the first layer stack such that sidewalls of each of the conductive layers are exposed within the opening; forming a second stack of layers within the opening, the second stack of layers including channel layers of semiconductor material positioned in the second stack such that each channel layer contacts exposed sidewalls of a respective conductive layer of the first layer stack; and forming transistor channels from the channel layers of the second stack such that each transistor channel extends between exposed sidewalls of a respective conductive layer within the opening.

[0008] Aspect (2) includes the method of claim **1**, wherein the forming a first layer stack includes depositing metal layers as the conductive layers.

[0009] Aspect (3) includes the method of claim **2**, wherein the depositing metal includes depositing a different metal material for each of the metal layers.

[0010] Aspect (4) includes the method of claim **2**, wherein the depositing metal includes depositing a same different metal material for each of the metal layers.

[0011] Aspect (5) includes the method of claim **1**, wherein: the forming an opening includes exposing a semiconductor surface of the substrate, and the forming a second stack includes epitaxially growing sacrificial layers of semiconductor material that alternate with the channel layers of semiconductor material in the second stack.

[0012] Aspect (6) includes the method of claim **5**, wherein the forming a second stack includes epitaxially growing sacrificial layers of SiGe material which provide etch selectivity with respect to the channel layers.

[0013] Aspect (7) includes the method of claim **1**, wherein the forming a second stack of layers includes forming each of the channel layers in the same plane as a respective conductive layer such that ends of the channel layers are aligned with sidewalls of the respective conductive layer.

[0014] Aspect (8) includes the method of claim **1**, wherein the forming a second stack of layers includes forming a plurality of second stacks of layers within the opening by etching an opening in the second stack that divides the second stack into a plurality of second stacks.

[0015] Aspect (9) includes the method of claim **1**, wherein: the forming an opening includes forming a plurality of openings in the first layer stack, the forming a second stack of layers includes forming a plurality of second stacks within the openings respectively, and forming transistor channels from the channel layers of each second stack.

[0016] Aspect (10) includes the method of claim **1**, wherein the forming transistor channels includes forming a gate-all-around (GAA) structure around each channel layer.

[0017] Aspect (11) includes the method of claim **10**, wherein the gate-all-around GAA structure includes: selectively depositing a high-k dielectric layer around the channel layer; and selectively depositing a gate metal on the high-k dielectric layer.

[0018] Aspect (12) includes a method of processing a substrate, the method including: forming a first stack of layers on a substrate, the first stack of layers including metal layers and dielectric layers that alternate in the first stack of layers; forming openings in the first stack of layers and depositing a first semiconductor layer in the openings uncovered in the first stack of layers such that the first semiconductor layer rests over the substrate; forming a

second stack of layers within the openings over the first semiconductor layer by epitaxial growth, the second stack of layers including second semiconductor layers and epitaxial layers that alternate in the second stack of layers and are aligned with respective layers of the first stack of layers; and forming transistor channels from the epitaxial layers of the second stack of layers in a same plane as the metal layers from the first stack of layers such that the transistor channels extend between the metal layers and the epitaxial layers within the openings.

[0019] Aspect (13) includes the method of claim **12**, further including: forming the openings in the first stack of layers by: depositing a mask layer over at least a portion of a capping layer that is deposited on top of the first stack of layers; and executing a first etching, the first etching etches portions of the first stack of layers not covered by the first mask layer to form the openings in the first stack of layers, wherein the openings in the first stack of layers are of a length equal to the a predetermined distance.

[0020] Aspect (14) includes the method of claim **13**, wherein the first mask layer includes a photoresist (PR) mask layer.

[0021] Aspect (15) includes the method of claim **12**, wherein the openings in the first stack of layers include a first opening and a second opening, and wherein the first opening and the second opening has a base that is formed by the substrate layer.

[0022] Aspect (16) includes the method of claim **15**, further including: forming a second stack of layers within each of the first opening and the second opening; and depositing another capping layer over each of the second stack of layers formed within the first opening and the second opening.

[0023] Aspect (17) includes the method of claim **16**, further including: depositing a second mask layer over the another capping layer of the second stack of layers, such that the second mask layer extends over the another capping layer to overlap a portion of the capping layer, wherein the width of the second mask layer equals to a second predetermined distance.

[0024] Aspect (18) includes the method of claim **17**, further including: executing a second etching on the second stack of layers, the second etching etches a first set of portions of the second stack of layers not covered by the second mask layer to form openings in the second stack of layers.

[0025] Aspect (19) includes the method of claim **18**, wherein a second set of portions of the second stack of layers covered beneath the second mask layer form a third stack of layers based on the second etching, wherein the third stack of layers are of a width equal to the second predetermined distance.

[0026] Aspect (20) includes the method of claim **19**, wherein the second set of portions of the second stack of layers covered beneath the second mask layer that form the third stack of layers includes a portion of the second semiconductor layers and a portion of the epitaxial layers.

[0027] The order of discussion of the different steps as described herein has been presented for the sake of clarity. In general, these steps can be performed in any suitable order. Additionally, although each of the different features, techniques, configurations, etc. herein may be discussed in different places of this disclosure, it is intended that each of the concepts can be executed independently of each other or in combination with each other. Accordingly, the present invention can be embodied and viewed in many different ways.

[0028] Note that this summary section does not specify every embodiment and/or incrementally novel aspect of the present disclosure or claimed invention. Instead, this summary only provides a preliminary discussion of different embodiments and corresponding points of novelty over conventional techniques. For additional details and/or possible perspectives of the invention and embodiments, the reader is directed to the Detailed Description section and corresponding figures of the present disclosure as further discussed below.

BRIEF DESCRIPTION OF THE DRAWINGS

[0029] A more complete appreciation of the invention and many of the attendant advantages thereof will be readily obtained as the same becomes better understood by reference to the following detailed description when considered in connection with the accompanying drawings, wherein:

[0030] FIG. **1** illustrates a first stack of layers with alternating layers of dielectric material and metal material, according to certain embodiments.

[0031] FIG. **2** illustrates applying a plurality of first mask layers over a first capping layer deposited on the first stack of layers of FIG. **1**, according to certain embodiments.

[0032] FIG. **3** illustrates etching of the first stack of layers of FIG. **2**, according to certain embodiments.

[0033] FIG. **4** illustrates depositing a second stack of layers with alternating semiconductor layers and epitaxial layers in etched regions of FIG. **3**, according to certain embodiments.

[0034] FIG. **5** illustrates a top view of FIG. **4**, according to certain embodiments.

[0035] FIG. **6** illustrates depositing a second capping layer over the second stack of layers of FIG. **5**, according to certain embodiments.

[0036] FIG. **7** illustrates a top view of FIG. **6**, according to certain embodiments.

[0037] FIG. **8** illustrates a top view of FIG. **7** with a plurality of second mask layers applied over each of the second capping layers such that it extends to partially overlap the first capping layer, according to certain embodiments.

[0038] FIG. **9** illustrates a top view of FIG. **8** after etching the second stack of layers and indicating a cross section side view line (AA') and a cross section side view line (BB') of the first stack of layers, according to certain embodiments.

[0039] FIG. **10** illustrates a cross section side view along the line (AA') of the first stack of layers after etching the second stack of layers to form a third stack of layers, according to certain embodiments.

[0040] FIG. **11** illustrates a cross section side view along the line (BB') of the first stack of layers after etching the second stack of layers to form the third stack of layers in FIG. **10**, according to certain embodiments.

[0041] FIG. **12** illustrates a cross section side view of FIG. **10** along the line (AA') by removing a semiconductor (SiGe2) layer underlying the third stack of layers and depositing a dielectric layer to replace the removed semiconductor layer, according to certain embodiments.

[0042] FIG. **13** illustrates a cross section side view of FIG. **11** along the line (BB') by removing a semiconductor (SiGe2) layer underlying the third stack of layers and

depositing a dielectric layer to replace the removed semiconductor layer, according to certain embodiments.

[0043] FIG. **14** illustrates a cross section side view of FIG. **12** along the line (AA') of the first stack of layers by removal of the semiconductor (SiGex) layers from the third stack of layers, according to certain embodiments.

[0044] FIG. **15** illustrates a cross section side view of FIG. **13** along the line (BB') of the first stack of layers upon removal of the semiconductor (SiGex) layers from the third stack of layers, according to certain embodiments.

[0045] FIG. **16** illustrates a cross section side view of FIG. **14** along the line (AA') of the first stack of layers by depositing high-k dielectric layers in the third stack of layers, according to certain embodiments.

[0046] FIG. **17** illustrates a cross section side view of FIG. **15** along the line (BB') of the first stack of layers by depositing the high-k dielectric layers in the third stack of layers, according to certain embodiments.

[0047] FIG. **18** illustrates a cross section side view of FIG. **16** along the line (AA') of the first stack of layers after etching of the first capping layer and the second capping layer and deposition of metal gate stack layers, according to certain embodiments.

[0048] FIG. **19** illustrates a cross section side view of FIG. **17** along the line (BB') of the first stack of layers after etching of the first capping layer and the second capping layer and deposition of the metal gate stack layers in the third stack of layers, according to certain embodiments.

[0049] FIG. **20** illustrates a cross section side view of FIG. **18** along the line (AA') of the first stack of layers after deposition of a dielectric material followed by chemical mechanical polishing, according to certain embodiments.

[0050] FIG. **21** illustrates a cross section side view of FIG. **19** along the line (BB') of the first stack of layers after deposition of the dielectric material followed by chemical mechanical polishing, according to certain embodiments.

[0051] FIG. **22** illustrates a data flow diagram for an exemplary method of processing a substrate, according certain embodiments.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

[0052] 3D integration, i.e. the vertical stacking of multiple devices, aims to overcome scaling limitations experienced in planar devices by increasing transistor density in volume rather than area. Although device stacking has been successfully demonstrated and implemented by the flash memory industry with the adoption of 3D NANO, application to random logic designs is substantially more difficult. 3D integration for logic chips (CPU (central processing unit), GPU (graphics processing unit), FPGA (field programmable gate array, SoC (System on a chip)) is being pursued.

[0053] Techniques herein enable higher density circuits to be produced at a reduced cost. Embodiments include 3D Horizontal Nano sheets with gate-all-around (GAA) architecture logic designs. N+S/D and P+S/D metal stacks can be customized with the techniques herein.

[0054] Techniques herein include methods for forming GAA transistor structures. Techniques include forming a first stack of layers that includes metal layers alternating with dielectric layers. Openings are formed within the first stack of layers to grow a second layer stack by epitaxial growth. The second layer stack includes alternating layers of semiconductor material that can be etched selective to other semiconductor materials. Transistor channels are formed from a portion of the semiconductor layers that are in plane with metal layers. The transistor channel structures extending from metal line to metal line in a given plane. The metal lines already connected to the transistor structures can function as local interconnects, facilitating connections to a vertical stack of lateral GAA transistors.

[0055] Of course, the order of discussion of the different steps as described herein has been presented for clarity's sake. In general, these steps can be performed in any suitable order. Additionally, although each of the different features, techniques, configurations, etc. herein may be discussed in different places of this disclosure, it is intended that each of the concepts can be executed independently of each other or in combination with each other. Accordingly, the present invention can be embodied and viewed in many different ways.

[0056] In the drawings, like reference numerals designate identical or corresponding parts throughout the several views. Further, as used herein, the words "a," "an" and the like generally carry a meaning of "one or more," unless stated otherwise. The drawings are generally drawn to scale unless specified otherwise or illustrating schematic structures or flowcharts.

[0057] Furthermore, the terms "approximately," "approximate," "about," and similar terms generally refer to ranges that include the identified value within a margin of 20%, 10%, or preferably 5%, and any values there between.

[0058] Techniques herein provide advanced processes to form metal lines in three dimensional (3D) devices. Embodiments include combining a 3D stack of alternating metal and dielectric layers with a 3D stack of horizontal nanosheet devices for enhancement of transistor performance. N+S/D (Source/Drain) and P+S/D metal stacks can be customized with the methods herein. Embodiments enable improved device performance Idsat (Drain current saturation), which is achieved because very high electron and hole concentrations are enabled with self-aligned S/D regions. Wiring layout alignment herein may be executed prior to the nanosheet formation for a more efficient circuit layout as an option. Techniques enable horizontal nanosheets/wires with GAA architecture logic designs. Other embodiments include complementary field-effect transistors (CFET), side-by-side vertical stacks of transistors, and many 3D device structures.

[0059] Techniques herein will now be described with reference to the accompanying drawings. An example process flow is described in FIGS. **1-21**. The example process provides stacks of 3D GAA horizontal nano-sheet devices side-by-side using a 3D layer stack of metal and dielectric layers for high-performance CMOS devices.

[0060] In FIG. **1**, a layer stack is deposited on a substrate. A cross-sectional substrate segment is illustrated. The layer stack includes alternating layer of dielectric material and metal (conductive material). The example embodiment of FIGS. **1-21** will include three transistors with GAA horizontal nanosheets. While three transistors layers are shown in this invention example, many more layers (N layers) can be used for 3D device formation herein.

[0061] As seen in FIG. **1**, a first stack of layers **101** is deposited on a substrate **102** with a first capping layer **104** deposited on top of the first stack of layers **101**. FIG. **1** illustrates a cross-sectional segment of the substrate **102**.

The first stack of layers **101** includes dielectric layers **106**, **110**, **114**, and **118** that alternate with conductive layers **108**, **112**, and **116**.

[0062] The dielectric material of the layers **106**, **110**, **114**, and **118** may include a low K dielectric material such as Nanopourous Silica, Hydrogensilsesquioxanes (HSQ), Teflon-AF (Polytetrafluoethylene or PTFE), and/or Silicon Oxyflouride (FSG), although any other suitable type of dielectric material may be used. Further, the dielectric layers **106**, **110**, **114** and **118** may be made of the same dielectric material or different dielectric materials.

[0063] The conductive layers **108**, **112**, and **116** may be any conductive material such as metal and may include lithium, titanium, titanium nitride layer (TiN), tungsten, and/or metal nitrite, although any other type of conductive material may also be included. Further, the layers **108**, **112**, and **116** may be made of the same conductive material or different conductive materials.

[0064] The type of material utilized to form the conductive layers **108**, **112**, and **116** may be tailored to the type of transistor that the conductive layer will connect to. By way of an example, an NMOS transistor type may use a first type of metal referred to as "metal 1," while a PMOS transistor type may use a second type of metal referred to as "metal 2." In the example embodiment of FIGS. **1-21**, the layer **108** is made of metal 1 which connects to an NMOS device, and the layers **112** and **116** are made of metal 2 which connects to PMOS devices. The type of metal generally depends on circuit requirements which will determine the Vt (i.e. threshold voltage) of the NMOS or PMOS devices. Also the thickness of high-k gate dielectric and type of High K material will also factor into this metal selection as well as the thickness of the high K gate dielectric material. Also stacks of metals may be utilized to further fine tune this Vt. Some metals as examples are group comprising ruthenium, Ru, tantalum nitride, TaN, titanium nitride, TiN, and tungsten, TiC, Ga, Gd, TiON, W, TaSiN, TiSiN, Mo, WN, Al,Cu and combinations thereof. In alternative embodiments, the conductive layers **108**, **112**, and **116** may all be made of the same material, or may all be made of different materials from one another.

[0065] The substrate **102** further includes buried power rails **120** placed in the substrate **102** below the active devices. In another embodiment, the power rails may not be buried in the substrate **102** and instead, the power rails may be external to the substrate **102** such as above the active devices.

[0066] FIGS. **2** and **3** illustrate the forming of openings in the first stack of alternating dielectric and conductive layers **101**. As seen in FIG. **2**, a mask layer **126** is deposited over the first capping layer **104**. The mask layer **126** can be a photoresist (PR). The mask layer **126** is patterned such that there are open spaces **128** of a first predetermined length L**1** and L**2** in the mask layer **126**. While FIG. **2** shows L**1** and L**2** as equal length, the length L**1** and L**2** may not be equal to each other. Although, mask layer **126** illustrated has two open spaces **128**, any number of open spaces may be formed in the mask layer **126**.

[0067] Referring now to FIG. **3**, the first stack of layers **101** is etched using the mask layer **126** to open future 3D nano-sheet regions. That is, with an etch mask layer **126** in place, the first stack of layers **101** can be directionally etched through all of the layers in the layer stack or at least etching through metal layers. The openings formed herein can define the L dimension of the device for this example three-transistor stack. In the embodiment of FIG. **3**, first opening **132-1** and second opening **132-2** are etched through all of the layers **106**, **108**, **110**, **112**, **114**, **116**, **118**, and **104** to expose the underlying substrate **102** in regions not covered by the mask layer **126**. Exposure of the underlying substrate permits epitaxial growth of semiconductor layers within the openings **132-1** and **132-2** as will be discussed below. The first opening **132-1** and the second opening **132-2** are of lengths equal to L**1** and L**2** corresponding to the mask opening dimensions, respectively. Note that L**1** and L**2** can have different dimensions or can be of the same dimensions as defined by the mask layer **126**.

[0068] The etch mask is removed after etching the first stack of layers **101**, followed by growing second stacks in the openings formed in the first stack of layers **101**. The first stack of layers **101** is also referred to as a first layer stack **101**. The second stacks can include alternating layers of semiconductor material. For example, the alternating layers of the second stack can include (from the bottom up) SiGe2, SiGex, epi channel 1, SiGex, epi channel 2, SiGex, epi channel 3, and SiGex. Note that one or more stacks can be formed depending on 3D circuit layout requirements. The example process flow of FIGS. **1-21** illustrates an embodiment including two NMOS devices in upper and lower positions of the stack (Metal 2 suitable for NMOS device) with one PMOS device in center (Metal 1 suitable/selected for PMOS device). FIG. **4** illustrates this example. FIG. **4** shows removal of the mask layer **126** of FIG. **3**, followed by depositing second stacks **133-1** and **133-2** in the openings **132-1** and **132-2** respectively. Each second stack **133-1** and **133-2** includes alternating layers made of (from the bottom up) a SiGe2 layer **134**, a SiGex layer **136**, an epi channel 1 layer138, a SiGex layer **140**, an epi channel 2 layer **142**, a SiGex layer **144**, an epi channel 3 layer **146**, and a SiGex layer **148**. The epi channel 1 material, epi channel 2 material, and epi channel 3 material may be a different material or the same material. The epi channel 1 material, epi channel 2 material and epi channel 3 material may include any single crystal semiconductor or compound semiconductor. Some examples include Si, SixGe1-x, Ge, SixC1-x, GexSny, The channel may also either be intrinsic or doped N+ or P+ as other options depending on circuit requirements (SiB, GeAs, SiP, SiAs as some doping examples). Further, the SiGex layers **136**, **140** and **144** may be of any suitable composition that permits selectivity with respect to the epi channel layers **138**, **142**, and **146**. FIG. **5** is a top view of FIG. **4**. Future channel regions of the transistors will be beneath SiGex layer **148**, and metal S/D regions will be beneath capping layer **104**, as will be discussed further below.

[0069] As shown in FIGS. **6** and **7**, a second capping layer **166** is deposited and planarized on the substrate. This essentially adds a capping layer over the epitaxial stacks. Specifically, FIG. **6** illustrates a second capping layer **166** deposited over the layer **148** made of the SiGex material. In the example embodiment of FIGS. **1-21**, the second capping layer **166** is of a different material from the first capping layer **104** such that the capping layer **166** is selective to capping layer **104**.

[0070] FIG. **7** illustrates a top view of FIG. **6**, in which regions of the second capping layer **166** are surrounded by the first capping layer **104**. In some embodiments, layer **166** and second stacks **133-1**, **133-2** having dimensions that correspond to the channel regions of the final GAA transis-

tors within each stack. For example, in the top view of FIG. **7**, the second stacks **133-1** and **133-2** may provide both the length and width dimensions of the channel of each GAA transistor within the stack. However, in the example process flow of FIGS. **1-21**, the second stacks **133-1** and **133-2** are further divided into smaller stacks defining the transistor channel width.

[0071] FIGS. **8-11** show the formation of four second stacks below the mask layer **170** that will each provide three stacked GAA transistors for a total of **12** GAA transistors. The substrate is masked (FIG. **8**, which is a top view). Future channel regions are beneath SiGex, and metal S/D regions are beneath capping layer. FIG. **8** illustrates the top view of FIG. **7** with a mask layer **170** deposited over the first capping layer **104** and second capping layer **166**. The mask layer **170** is also referred to as a second mask layer pattern, and can be a PR mask layer. As seen in FIG. **8**, the second mask layer **170** is patterned to provide four regions of PR material each of which extends over the second capping layer **166** and overlaps portions of the first capping layer **104**. That is, the mask layer **170** is deposited over the layer **166** such that masked regions of the mask layer **170** are greater in length than the lengths L**1** and L**2**. Each of the four regions of the mask layer **170** will define a respective second stack of epitaxially grown semiconductor material. Further, each of the four regions of mask layer **170** defines a channel width for transistors within its stack. Example widths W**1** and W**2** are shown. The widths W**1** and W**2** may be the same or different.

[0072] FIG. **9** shows top view after etching the epi stack within openings and removing the etch mask. Specifically, FIG. **9** illustrates a top view of FIG. **8** upon removal of the mask layer **170** and etching of portions of the stacked layers not covered by the mask layer **170**. The etching exposes regions of the dielectric layer **106** and generates four of the second stacks **180-1**, **180-2**, **180-3** and **180-4**. FIG. **9** also illustrates the line AA' and the line BB' utilized to illustrate a side view of a cross-section of the region along the lines below.

[0073] FIG. **10** shows a side view cross-section through cut line AA' passing through second stacks **180-1** and **180-2**. The stack **180-1** has a width W**1** the stack **180-2** has a width W**2**. Accordingly, each second stack **180-1** and **180-2** includes layers **134**, **136**, **138**, **140**, **142**, **144**, **146**, and **148** underneath the capping layer **166**. The layers are formed by etching of the alternating layers **134**, **136**, **138**, **140**, **142**, **144**, **146**, and **148** (as illustrated previously in FIG. **4**) of the first stack **100**. Note that opposing sides of the metal layers **108**, **112** and **116** of the first stack **100** are not connected to channel regions formed by epi channel layers **138**, **142** and **146** due to the openings **184**. This space within the openings **184** may be used for additional routing features.

[0074] FIG. **11** shows a side view cross-section through cut line BB' passing through stacks **180-1** and **180-3**. As seen, the stack **180-3** has a width W**1** and includes layers **134**, **136**, **138**, **140**, **142**, **144**, **146**, and **148** underneath the capping layer **166**. The layers are formed by etching of the alternating layers **134**, **136**, **138**, **140**, **142**, **144**, **146**, and **148** (as illustrated previously in FIG. **4**) of the first stack **100**. As seen, the layers of the first stack **101** are a same thickness as the layers of each second stacks **180-1**, **180-2**, **180-3**, and **180-4** such that the metal layers **108**, **112** and **116** are vertically aligned to contact opposing ends of the epi channel layers **138**, **142** and **146**. Thus, the metal for S/D regions are connected to the channel regions and are self-aligned for the L direction cross section along BB'.

[0075] FIG. **12** illustrates through cut line AA' after replacing SiGe2 layer **134** (bottom layer of epi stack) with Dielectric **2** **186**, while FIG. **13** illustrates the structure of FIG. **12** through cut line BB'. Although FIG. **10** shows the dielectric material **106** as having the same thickness as the SiGe2 layer **134** at the bottom of the stacks, those skilled in the art will understand that the thickness of the dielectric material **106** must be less than that of the SiGe2 layer **134** so that the layer **134** is exposed for selective etching and selective deposition of Dielectric 2 **186**.

[0076] FIGS. **14** and **15** illustrate releasing the channel regions of each epi stack. FIG. **14** shows a side cross-section after removal of SiGex layers from the epi stacks **180-1** and **180-2** by selective etching. The second stacks **180-1** and **180-2** are supported by the first stack **100** as shown in the BB' cross-section in FIG. **15**.

[0077] After releasing of the epi channel layers **138**, **142** and **146** of each stack, the gate-all-around (GAA) structure is formed around each of these layers as shown in FIGS. **16-19**. First, a selective high-k deposition is executed that deposits high-k material on uncovered epi channels. FIG. **16** illustrates a side view cross-section through the cut line AA' of FIG. **14** after deposition of a high-k gate material on the exposed surfaces of the epi channel layers.

[0078] Specifically, high-k gate layers **200** are selectively deposited on the exposed surfaces of the layers **138**, **142** and **146** of each stack. As seen, a high-k layer **200** surrounds each of the epi channel layers.

[0079] FIG. **17**, illustrates the side view cross-section through the cut line BB' of FIG. **15** after deposition of a high-k gate layer **200** made of a high-k gate material on the exposed surfaces of the layers **138**, **142** and **146**. Note that in this view the high-k layer **200** does not cover opposing sides of the epi channel layers **138**, **142** and **146** because the metal and dielectric of the first stack of layers **101** prevents deposition on these surfaces.

[0080] Next a metal stack can be formed on the high-k layers surrounding the channels. This can be executed by a conformal deposition followed by etching excess material, or by selective deposition. FIGS. **18-19** show side cross-sectional views after forming gate stacks and removed hardmasks. Specifically, FIG. **18** illustrates a side view cross-section through the cut line AA' of FIG. **16** As seen, metal gate layers **236** are deposited over the high-k gate layers **200**.

[0081] FIG. **19** illustrates the side view cross-section through the cut line BB' of FIG. **17** after deposition of the metal gate layers **236** over the high-k gate layers **200**. Forming of the gate metal layers **236** completes the formation of transistor channels **300-1** of stack **180-1** and transistor channels **300-2** of stack **180-2**. In the example shown, the transistors are junctionless transistors in which the interface of the metal layers with the channel layer for source/drain regions of the transistor. Transistor channels are also completed for stacks **180-3** and **180-4**.

[0082] In FIGS. **20-21**, a dielectric is deposited to fill openings surrounding the horizontal channels. This shows a vertical stack of three transistors. As can be appreciated, many more transistors can be stacked.

[0083] FIG. **20** illustrates a side view cross-section through the cut line AA' of FIG. **18** with a filling material **264** deposited to fill the open spaces **184**. FIG. **21**, illustrates

the side view cross-section through cut line BB' of FIG. **19** after deposition of the filling material **264** deposited to fill the open spaces in the third stack **183** and the fifth stack **183**. The filling material **264** may be a dielectric material.

[0084] FIG. **22** illustrates a data flow diagram **2200** of a non-limiting example of processing a substrate. In step **2202**, a first layer stack **101** is formed on a substrate **102**, the first layer stack **101** including metal layers (**108**, **112**, and **116** of FIG. **1**) and dielectric layers (**106**, **110**, **114**, and **118** of FIG. **1**) that alternate in the first layer stack **101**.

[0085] In step **2204**, openings (**132-1** and **132-2** of FIG. **3**) are formed in the first layer stack **101**, such that a semiconductor layer **102** positioned under the first layer stack **101** is uncovered.

[0086] In step **2206**, a second stack of layers (**133-1** of FIG. **4**) is formed within the openings (**132-1**) from the semiconductor layer **102** by epitaxial growth, the second stack of layers (**133-1**) including alternating layers of semiconductor material (**134**, **136**, **138**, **140**, **142**, **144**, **146**, and **148** of FIG. **4**) aligned with respective layers of the first layer stack **101**.

[0087] In step **2208**, transistor channels (**300-1** and **300-2** of FIG. **18**) are formed from the semiconductor layers of the second stack of layers (**133**) in a same plane as metal layers (**108**, **112**, and **116**) from the first stack **101**, such that the transistor channels formed by the epi channel layers (**138**, **142**, and **146**) extend between given metal layers (**108**, **112**, and **116**) within the openings (**132-1** and **132-2**).

[0088] In the preceding description, specific details have been set forth, such as a particular geometry of a processing system and descriptions of various components and processes used therein. It should be understood, however, that techniques herein may be practiced in other embodiments that depart from these specific details, and that such details are for purposes of explanation and not limitation. Embodiments disclosed herein have been described with reference to the accompanying drawings. Similarly, for purposes of explanation, specific numbers, materials, and configurations have been set forth in order to provide a thorough understanding. Nevertheless, embodiments may be practiced without such specific details. Components having substantially the same functional constructions are denoted by like reference characters, and thus any redundant descriptions may be omitted.

[0089] Various techniques have been described as multiple discrete operations to assist in understanding the various embodiments. The order of description should not be construed as to imply that these operations are necessarily order dependent. Indeed, these operations need not be performed in the order of presentation. Operations described may be performed in a different order than the described embodiment. Various additional operations may be performed and/or described operations may be omitted in additional embodiments.

[0090] "Substrate" or "target substrate" as used herein generically refers to an object being processed in accordance with the invention. The substrate may include any material portion or structure of a device, particularly a semiconductor or other electronics device, and may, for example, be a base substrate structure, such as a semiconductor wafer, reticle, or a layer on or overlying a base substrate structure such as a thin film. Thus, substrate is not limited to any particular base structure, underlying layer or overlying layer, patterned or un-patterned, but rather, is contemplated to include any such layer or base structure, and any combination of layers and/or base structures.

[0091] The description may reference particular types of substrates, but this is for illustrative purposes only. Those skilled in the art will also understand that there can be many variations made to the operations of the techniques explained above while still achieving the same objectives of the invention. Such variations are intended to be covered by the scope of this disclosure. As such, the foregoing descriptions of embodiments of the invention are not intended to be limiting. Rather, any limitations to embodiments of the invention are presented in the following claims.

1. A method of processing a substrate, the method comprising:

forming a first layer stack on a substrate, the first layer stack including conductive layers and dielectric layers that alternate in the first layer stack;

forming an opening in the first layer stack, the opening extending through each of the conductive layers in the first layer stack such that sidewalls of each of the conductive layers are exposed within the opening;

forming a second stack of layers within the opening, the second stack of layers including channel layers of semiconductor material positioned in the second stack of layers such that each channel layer contacts exposed sidewalls of a respective conductive layer of the first layer stack; and

forming transistor channels from the channel layers of the second stack such that each transistor channel extends between exposed sidewalls of a respective conductive layer within the opening.

2. The method of claim **1**, wherein the forming a first layer stack comprises depositing metal layers as the conductive layers.

3. The method of claim **2**, wherein the depositing metal comprises depositing a different metal material for each of the metal layers.

4. The method of claim **2**, wherein the depositing metal comprises depositing a same metal material for each of the metal layers.

5. The method of claim **1**, wherein:

the forming an opening comprises exposing a semiconductor surface of the substrate, and

the forming a second stack comprises epitaxially growing sacrificial layers of semiconductor material that alternate with the channel layers of semiconductor material in the second stack.

6. The method of claim **5**, wherein the forming a second stack comprises epitaxially growing sacrificial layers of SiGe material which provide etch selectivity with respect to the channel layers.

7. The method of claim **1**, wherein the forming a second stack of layers comprises forming each of the channel layers in a same plane as a respective conductive layer such that ends of the channel layers are aligned with sidewalls of the respective conductive layer.

8. The method of claim **1**, wherein the forming a second stack of layers comprises forming a plurality of second stacks of layers within the opening by etching an opening in the second stack that divides the second stack into a plurality of second stacks.

9. The method of claim **1**, wherein:
the forming an opening comprises forming a plurality of openings in the first layer stack,
the forming a second stack of layers comprises forming a plurality of second stacks within the openings respectively, and
forming transistor channels from the channel layers of each second stack of layers.

10. The method of claim **1**, wherein the forming transistor channels comprises forming a gate-all-around (GAA) structure around each channel layer.

11. The method of claim **10**, wherein the gate-all-around GAA structure comprises:
selectively depositing a high-k dielectric layer around the channel layer; and
selectively depositing a gate metal on the high-k dielectric layer.

12. A method of processing a substrate, the method comprising:
forming a first stack of layers on a substrate, the first stack of layers including metal layers and dielectric layers that alternate in the first stack of layers;
forming openings in the first stack of layers and depositing a first semiconductor layer in the openings uncovered in the first stack of layers such that the first semiconductor layer rests over the substrate;
forming a second stack of layers within the openings over the first semiconductor layer by epitaxial growth, the second stack of layers including second semiconductor layers and epitaxial layers that alternate in the second stack of layers and are aligned with respective layers of the first stack of layers; and
forming transistor channels from the epitaxial layers of the second stack of layers in a same plane as the metal layers from the first stack of layers such that the transistor channels extend between the metal layers and the epitaxial layers within the openings.

13. The method of claim **12**, further comprising:
forming the openings in the first stack of layers by:
depositing a first mask layer over at least a portion of a capping layer that is deposited on top of the first stack of layers; and
executing a first etching, the first etching etches portions of the first stack of layers not covered by the first mask layer to form the openings in the first stack of layers, wherein the openings in the first stack of layers are of a length equal to the a predetermined distance.

14. The method of claim **13**, wherein the first mask layer includes a photoresist (PR) mask layer.

15. The method of claim **12**, wherein the openings in the first stack of layers include a first opening and a second opening, and wherein the first opening and the second opening has a base that is formed by the substrate layer.

16. The method of claim **15**, further comprising:
forming a second stack of layers within each of the first opening and the second opening; and
depositing another capping layer over each of the second stack of layers formed within the first opening and the second opening.

17. The method of claim **16**, further comprising:
depositing a second mask layer over the another capping layer of the second stack of layers, such that the second mask layer extends over the another capping layer to overlap a portion of the capping layer, wherein a width of the second mask layer equals to a second predetermined distance.

18. The method of claim **17**, further comprising:
executing a second etching on the second stack of layers, the second etching etches a first set of portions of the second stack of layers not covered by the second mask layer to form openings in the second stack of layers.

19. The method of claim **18**, wherein a second set of portions of the second stack of layers covered beneath the second mask layer form a third stack of layers based on the second etching, wherein the third stack of layers are of a width equal to the second predetermined distance.

20. The method of claim **19**, wherein the second set of portions of the second stack of layers covered beneath the second mask layer that form the third stack of layers include a portion of the second semiconductor layers and a portion of the epitaxial layers.
