(57) **ABSTRACT**

A machine for dispensing beverages from a pod, includes a frame, a container including a pod-receiving zone, and an opening/closing device arranged between the frame and the container so as to pivot the container along a vertical axis between a closed position permitting the beverage to be dispensed and an open position permitting access to the pod-receiving zone, wherein the opening/closing device is configured such that the container has a 180° angular stroke for moving from the closed position to the open position and vice versa, such that a direction of rotation of the container can be clockwise or counter-clockwise, at the user's discretion.

CROSS-REFERENCE TO RELATED
APPLICATIONS

This application is the U.S. National Stage of PCT/FR2017/050242 filed Feb. 2, 2017, which in turn claims priority to French patent application number 1650912 filed Feb. 4, 2016. The content of these applications are incorporated herein by reference in their entireties.

TECHNICAL FIELD

This invention concerns a machine for dispensing beverages from a pod. Its main objective is to facilitate the manipulation of the machine when the pod is placed in a container on this machine and then when it is removed.

“Pod” means a capsule comprising one or more chambers, each chamber containing an ingredient forming part of the composition of the beverage, the ingredients being intended to be mixed with water during preparation of the beverage.

In a particular, non-restrictive embodiment, the pod consists of a capsule comprising one or more storage chambers, each storage chamber containing an ingredient, in particular a liquid, a channel allowing water to be dispensed, and a mixing chamber. The pod is configured to separate the mixing chamber from the at least one storage chamber and from the channel, in an initial mode, and to cause the mixing chamber to communicate with the at least one chamber and with the channel, in a beverage preparation mode. In addition, the machine comprises air injection means and water injection means, configured to perforate the pod and to inject air and water respectively into the at least one storage chamber and into the channel, in the beverage preparation mode. In this preparation mode, the air injected into the at least one storage chamber pushes the at least one ingredient into the mixing chamber and, concomitantly, the water injected into the channel is transferred into said mixing chamber, which allows the ingredient or ingredients to mix with the water before the beverage is released into a container, such as a glass or tumbler.

STATE OF THE ART

Patent applications or patents published under the numbers U.S. Pat. No. 4,829,889, EP1635680, EP1996051 and EP2564736 disclose machines for dispensing beverages from a pod.

According to this prior art, the beverage-dispensing machine comprises a frame, a container including a pod-receiving zone, and an opening/closing device arranged between the frame and the container so as to pivot said container between a closed position permitting the beverage to be dispensed and an open position permitting access to the pod-receiving zone.

In the documents U.S. Pat. No. 4,829,889 and EP2564736, the opening/closing device allows the container to be pivoted about a vertical axis. On the contrary, in the documents EP1635680 and EP1996051, the opening/closing device allows the container to pivot about a horizontal axis.

SUMMARY OF THE INVENTION

The objective of this invention is to implement a machine for dispensing beverages from a pod that presents the

2

aforementioned characteristics from the prior art, having an opening/closing device configured to pivot the container about a first vertical axis relative to the frame, that is ergonomic and suitable for all users, and that permits better access to the container.

For this purpose, according to the invention, the opening/closing device is configured such that the container has a 180° angular stroke for moving from the closed position to the open position and vice versa, such that the direction of rotation can be clockwise or counter-clockwise, at the user’s discretion. In this way, the container can be completely released in front of the machine, with respect to the frame, so as to permit suitable access to the pod-receiving zone during insertion or removal of said pod. In addition, the container can be manipulated easily, by left-handed as well as right-handed users, who can pivot said container clockwise or counter-clockwise during closing.

In a preferred embodiment of the machine according to the invention, the opening/closing device includes a system for orientation of the opening of the container configured to open the container in the direction opposite to the direction of the preceding closing. However, variants could be envisioned, with machines whose opening/closing device allows the container to be opened regardless of the direction of the closing that preceded the opening.

According to this preferred embodiment, the orientation system is configured to stop the container from pivoting when it reaches the closed position, said orientation system including a stop arranged on the frame and a stopping member arranged on the container. This makes it possible to precisely define the closing position in order to ensure that the machine functions properly during the dispensing of the beverage. Preferably, the stopping member of the container comprises a vertical rib arranged along an axis of rotation of the container. Preferably, the stop consists of a nose of a trigger able to move in rotation on either side of a middle position against two springs.

In a preferred embodiment of the machine according to the invention, the opening/closing device includes an opening assistance system configured to bring the container from the closed position to the open position by a 180° rotation. This allows the container to be opened in a precise manner without any manipulation of it by the user.

According to this preferred embodiment, the opening assistance system comprises a support member which cooperates with a plate secured to the container and arranged along the vertical axis of rotation of said container. In addition, the plate comprises at least one ramp on which said support member rests, such that the effort applied by the support member on the at least one ramp results in the rotation of the plate in at least one direction about the vertical axis. Preferably, the support member cooperates with a housing arranged on the container to keep the container in the open position. Preferably, the support member comprises a roller, limiting friction on the plate.

Advantageously, the machine comprises a locking/unlocking system configured to keep the container in the closed position with respect to the frame and, conversely, to release the container so that it can be pivoted to the open position.

In a preferred embodiment, the locking/unlocking system comprises, on the frame, a movable lock and means for controlling the lock and, on the container, a housing configured to receive the lock in the closed position. Preferably, the control means comprise a connecting rod secured to the

3

lock, a control button for the connecting rod and an element for returning the lock to the position maintaining the container.

In a preferred embodiment, the machine comprises an impulsion system configured to force the container to pivot when it is released by said locking/unlocking system. This allows the container to be released from its closed position, in order to then open it fully to 180°.

Advantageously, the machine comprises a detection system configured to detect the presence of a pod in the container when said container is in the closed position. This makes it possible to trigger the dispensing of the beverage only when a pod is present. In a preferred embodiment, the container comprises a vertical slot communicating with the pod-receiving zone. In addition, the detection system comprises a presence sensor and means for moving the presence sensor configured to move said sensor either to a position released from the slot during the initiation of the opening or closing of the container, or to a position engaged in the slot when the container has reached its closed position.

Advantageously, the machine comprises load transfer means arranged between the frame and the container, configured to stabilize the container when the machine is operating. Preferably, the load transfer means comprise at least one flange on the container and at least one support foot on the frame, said flange resting on said support foot in the closed position.

In one embodiment of the machine according to the invention, the container comprises means for gripping the pod in position in the receiving zone. This facilitates manipulation of the pod.

In one embodiment of the machine according to the invention, the container comprises a pod support part configured to be positioned in the pod-receiving zone and to receive said pod, said support part being removable. This facilitates cleaning of the machine.

Advantageously, the machine comprises a fluid-dispensing needle holder, a system for moving the needle holder from a position released from the pod to a position engaged on the pod, and a system for blocking the moving system, configured to keep the needle holder in the position released from the pod as long as the container has not returned to the closed position. This prevents damage to the needle holder during manipulation of the container.

BRIEF DESCRIPTION OF THE FIGURES

The following description demonstrates the characteristics and advantages of the beverage-dispensing machine covered by the invention, according to a preferred and non-restrictive design. This description is supported by figures, among which:

FIGS. 1 and 2 illustrate two overall views of a portion of the dispensing machine comprising the essential characteristics in relation to the invention, in particular the container that receives the pod, the container opening/closing device, the fluid-dispensing needle holder and the system for moving the needle holder, the container being respectively in the closed position and in the open position with respect to the frame;

FIG. 3 illustrates an overall view showing in particular the design of the container, which is in the open position;

FIG. 4 illustrates an overall view showing the container opening/closing device and the system for moving the needle holder, with the container in the open position;

4

FIGS. 5 and 6 illustrate two overall views showing the system for orientation of the opening of the container and the opening assistance system for said container, with the container in the open position;

FIG. 7 illustrates an overall view showing in particular the system for moving the needle holder;

FIGS. 8 and 9 illustrate two overall views showing in particular the container locking/unlocking device, in the unlocked position;

FIGS. 10 and 11 illustrate two overall views showing the container opening/closing device and the system for moving the needle holder, with the container in the closed position and the needle holder in the released position;

FIG. 12 illustrates an overall view showing the system for orientation of the opening of the container and the opening assistance system for said container, with the container in the closed position;

FIGS. 13 and 14 illustrate two overall views showing in particular the container locking/unlocking device, in the unlocked position;

FIG. 15 illustrates an overall view showing elements of the opening/closing device and the system for moving the needle holder, with the container in the closed position;

FIG. 16 illustrates an overall view showing in particular the system for moving the needle holder with the needle holder in the released position, and the container locking/unlocking system in the locked position;

FIGS. 17 and 18 illustrate two overall views showing a ramp on the system for moving the needle holder in the released position and the engaged position, respectively;

FIGS. 19 and 20 illustrate two overall views showing in particular the system for moving the needle holder in the engaged position;

FIG. 21 illustrates an overall view showing a wheel of the system for moving the needle holder, in the engaged position;

FIGS. 22 to 27 show a mode of design of a pod;

FIG. 28 illustrates an embodiment of the needles.

DETAILED DESCRIPTION

FIGS. 1 and 2 illustrate only the portions of the dispensing machine 1 implementing the invention. This machine 1 comprises other characteristics such as a fluid supply system and a system to manage the activation of this fluid supply system, which are not described below, as they are not essential to the implementation of the invention.

The machine 1 comprises a frame 2 and a container 3. The container 3 allows a pod 4 to be received. This container 3 is mounted with a pivoting connection with respect to the frame 2, about a first vertical axis X1 illustrated in particular in FIGS. 3 and 4. The container 3 can pivot from a closed position, illustrated in FIG. 1, to an open position, illustrated in FIG. 2, by rotating 180° about this vertical axis X1. And vice versa. In addition, the direction of rotation can be clockwise or counter-clockwise, at the user's discretion, as will be shown in detail below. For this purpose, the machine 1 comprises an opening/closing device 5 arranged between the frame 2 and the container 3, as illustrated for example in FIGS. 3, 4, 10, 11, 15 and 19.

This opening/closing device 5 comprises a system 6 for orientation of the opening of the container 3 and an opening assistance system 7, illustrated in particular in FIGS. 4, 5, 6, 11 and 12. The orientation system 6 allows the container 3 to be opened in the direction opposite to the direction of the preceding closing. The assistance system 7 allows the con-

5

tainer 3 to be brought from the closed position to the open position by a 180° rotation movement, without manipulation by the user.

The orientation system 6 comprises a rod 8 arranged along a second vertical axis X2, in a manner secured with respect to the frame 2. This rod 8 holds a trigger 9 pivotably mounted along the second vertical axis X2 and housed in a hollow area 10 of a part 11 which is fixed to the frame 2. In this way, the pivoting of the trigger 9 about the vertical axis X2 is limited by the lateral edges 10a, 10b of the hollow area 10.

The assistance system 7 comprises an axle 12 arranged along the first vertical axis X1. This axle 12 is mounted with a pivoting connection with respect to the frame 2 about the first vertical axis X1, and it is secured to the container 3. The orientation system 6 comprises a vertical rib 13 arranged on the axle 12 and configured to bear against a nose 14 of the trigger 9 during rotation of the axle 12.

Two springs 15a, 15b, indicated by portions of cylinders, are arranged between the lateral sides 9a, 9b of the trigger 9 and the lateral edges 10a, 10b of the hollow area 10, as illustrated in particular by FIGS. 5, 6 and 12. When the container 3 is in the open position, the vertical rib 13 is released, contrary to the nose 14 of the trigger 9 which is in the average equilibrium position in the area 10, as illustrated in particular by FIGS. 5 and 6.

During the closing of the container 3 by counter-clockwise rotation, illustrated by the arrow 16 on FIG. 12, the axle 12 and the vertical rib 13 turn about the vertical axis X1, said vertical rib 13 then bearing against the nose 14, which causes the trigger 9 to rotate clockwise, illustrated by the arrow 17 on FIG. 12. The spring 15b compresses until the lateral side 9b of the trigger 9 abuts against the lateral edge 10b of the hollow area 10, which stops the rotation of the container 3 in a precise position of closing illustrated in FIG. 1. The operating principle remains the same and is reversed when the container 3 is closed by turning it clockwise about the vertical axis X1, in which case the lateral side 9a of the trigger 9 turns counter-clockwise and abuts against the lateral edge 10a of the hollow area 10, the spring 15a being compressed in this case. The stopping position of the vertical rib 13 remains identical when it abuts against the nose 14 of the trigger 9, whether the container 3 is turned 180° clockwise or counter-clockwise during the closing. In addition, the presence of this trigger 9 abutting against one or the other of the lateral edges 10a, 10b of the hollow area 10, in the closed position, requires that the container 3 be opened in the direction opposite to the direction of the closing just performed.

A locking/unlocking system 18 allows the container 3 to be kept in the closed position with respect to the frame 2 and, conversely, allows the container 3 to be released so that it can be pivoted to an open position. This locking/unlocking system 18 will be described in more detail below. During unlocking, the release of the container 3 allows the spring 15a, 15b, which is in the compressed state, to relax and push the trigger 9 to cause it to pivot in the direction opposite to the direction of the preceding closing. The nose 14 then bears against the vertical rib 13, which forces the axle 12 to turn in the direction opposite to the direction of the preceding closing, thus giving an impulse to the container 3 and releasing it from the closed position.

The assistance system 7 comprises a plate 19 secured to the axle 12, this plate 19 comprising two ramps 20a, 20b arranged symmetrically with respect to a vertical plane P1 passing through the vertical axis X1, as illustrated in FIGS. 5, 6 and 12. These ramps 20a, 20b are slanted and form a top

6

21 and a housing 22 opposite said top 21. The assistance system 7 further comprises a support member 23 in the form of a hollow cylinder slidably mounted on the rod 8 along the second vertical axis X2. This support member 23 comprises a tab 24 which is arranged in a housing 25, as illustrated for example by FIGS. 3, 4 and 15. This housing 25 prevents the rotation of the tab 24, and thus ensures the mounting in translation of the support member 23 along the vertical axis X2. This support member 23 comprises a finger 26 equipped with a roller 27 mounted in rotation about a horizontal axis X3. This roller 27 bears against one or the other of the ramps 20a, 20b of the plate 19, according to the direction of rotation of the container 3. A spring (not illustrated) is arranged on the rod 8 along the axis X2 to apply a downward retraction force on the support member 19, which forces said container 3 to turn from the closed position to the open position, once said container 3 is released by the locking/unlocking device 18. In the closed position, the roller 27 is situated at the top 21 on the plate 19, in a position of equilibrium. The impulse given by the impulse system consisting of the springs 15a, 15b, of the trigger 9 and of the vertical rib 13, allows the trigger 27 to be engaged on one or the other of the ramps 20a, 20b according to the direction of rotation, the assistance system 7 then ensuring the complete opening of the container 3. In the open position, the roller 27 is positioned in the housing 22 on the plate 19, which ensures that the container 3 is suitably and stably kept in this open position.

As illustrated in FIGS. 5, 6 and 12, the ramps 20a, 20b on the plate 19 each comprise at least two different slope zones 28a, 28b allowing two torques to be applied to the container 3 during its opening. This makes it possible to reduce the load on the container 3 at the end of opening of the latter. In addition, the machine 1 comprises a buffer system 29, illustrated for example in FIGS. 4 and 11, configured to buffer the container 3 during its rotation to the open position. The buffer system 29 comprises a pinion 30 secured to the axle 12, which meshes with a sprocket wheel 31 secured to an oil buffer 32.

The machine 1 comprises a locking/unlocking system 18, illustrated in particular in FIGS. 2, 3, 4, 8, 9, 13, 14, 15 and 20, which allows the container 3 to be kept in a closed position with respect to the frame 2, in which position the beverage can be dispensed when a pod 4 is present in a receiving zone 33 of said container 3. The locking/unlocking system 18 comprises a movable lock 34, means 35 for control of the lock 34, arranged on the frame 2, and a housing 36 arranged on the container 3, this housing 36 being configured to receive the lock 34 when the container 3 is in the closed position. The control means 35 comprise a connecting rod 37 whose lower extremity 37a is secured to the lock 34. The connecting rod 37 is mounted with a pivoting connection 38 about a horizontal axis X4 with respect to the frame 2. The control means 35 also comprise a control button 39 mounted in translation along a vertical axis X5 with respect to the body 40. This control button 39 comprises a finger 41 which bears against the upper extremity 37b of the connecting rod 37, as illustrated in FIG. 9, in a determined position of said body 40, as will be explained below. This finger 41 is arranged vertically and off-center with respect to the vertical axis X5 of translation of the control button 39. A press on the control button 39 lowers the finger 41 which rests on the upper extremity 37b of the connecting rod 37, allowing it to pivot about the horizontal axis X4, and thus allowing the lock 34 to be released from the housing 36 on the container 3, which allows the container 3 to pivot to the open position, as explained previ-

ously. In addition, the control means **35** comprise a return element (not illustrated) of the lock **34**, in the form of a spring, which applies force on the lock **34** and/or on the connecting rod **37** so as to ensure that said lock **34** returns to the position maintaining the container **3**.

As illustrated in particular with regard to FIGS. **2**, **3**, **4**, **8**, **9**, **13**, **14**, **16** and **20**, a second connecting rod **42** has its lower extremity **42a** mounted in pivoting connection **43** about a horizontal axis **X6**, with respect to the frame **2**. The second connecting rod **42** comprises an opening **44** extending on a portion of its length, this opening **44** receiving a lug **45** arranged on the first connecting rod **37** secured to the lock **34**. A presence sensor **46**, such as a strip sensor, is secured at the upper extremity **42b** of the second connecting rod **42**. During pressure on the control button **39**, the lower extremity **37a** of the first connecting rod **37** pivots backwards about the horizontal axis **X4**. The lug **45** then applies a force to the second connecting rod **42**, allowing the presence sensor **46** to pivot backwards about the horizontal axis **X6**. When the pressure on the control button **39** stops, the return element of the lock **34** acts in the opposite way on the first connecting rod **37**, which itself acts on the second connecting rod **42**, ensuring that the presence sensor **46** pivots forwards. The container **3** comprises a slot **47** allowing a portion of the contour **48** of the pod **4** to appear, when the latter is present in the receiving zone **33**, as illustrated in particular in FIGS. **2**, **3** and **16**. When the presence sensor **46** is pivoted backwards, the latter is released from the slot **47**, which allows the container **3** to pivot without interfering on the presence sensor **46**. Conversely, when the presence sensor **46** is pivoted forwards, the latter penetrates the slot **47** and can come into contact with the wall **48** of the pod **4** or come into proximity with the latter, which allows the detection of the presence of said pod **4** in the receiving zone **33** of the container **3**. The lock **34** comprises two slightly beveled teeth **49a**, **49b** which respectively abut against two points of contact **50a**, **50b** on the container **3**, during the pivoting of said container **3** in the closed position, in the clockwise direction or, conversely, in the counter-clockwise direction. Thus, during the closing of the container **3** by pivoting it clockwise, the first point of contact **50a** abuts against the first tooth **49a**. Conversely, during the closing of the container **3** by pivoting it counter-clockwise, the second point of contact **50b** abuts against the second tooth **49b**. The beveled shape of the teeth **49a**, **49b** and the circular shape of the container **3** allow the lock **34** to be pushed backwards while allowing the container **3** to slide to its closed position. The backwards movement of the lock **34** concomitantly ensures the movement of the presence sensor **46**, by means of the connecting rods **37**, **42**, which avoids any interference between the presence sensor **46** and the container **3** during the closing. Once the container **3** is in the closed position, the return element (not illustrated) ensures that the lock **34** returns to position in the housing **36**, and that the presence sensor **46** returns to position in the slot **47**.

The machine **1** comprises a needle holder **51** and a system **52** for moving the needle holder **51** from a position released from the pod **4**, illustrated in FIGS. **10** and **16**, to a position engaged on the pod **4**, illustrated in FIG. **19**. The needle holder **51** receives three needles **53a**, **53b**, **53c** connected to conduits **54a**, **54b**, **54c** allowing fluids to be dispensed, as illustrated in FIGS. **7** and **16**. The number of needles and the types of fluids dispensed, in particular air or water, depend on the design of the pod **4**. In this instance, the machine **1** is configured to receive a pod **4** comprising two storage chambers **55a**, **55b**, each storage chamber containing an ingredient (not illustrated), and a channel **56** for dispensing

water, as illustrated in FIG. **25**. During the move from the released position to the engaged position, the needles **53a**, **53b**, **53c** perforate the seal **57** of the pod **4** illustrated in FIG. **22**, and position themselves respectively in the upper parts of the two storage chambers **55a**, **55b** and of the channel **56**.

The moving system **52** comprises a control member **58** which comprises the aforementioned body **40**. This body **40** is preferably equipped with three spiral ramps **59** uniformly distributed around its cylindrical wall, for a better distribution of load. The body **40** comprises a circular throat **60** which receives three first pins **61** uniformly distributed around this throat **60** and secured to an element **62** of the frame **2**, as illustrated for example by FIGS. **15** and **18**. This allows the body **40** to be mounted in pivoting connection about the vertical axis **X5**, with respect to the frame **2**. The control member **58** also comprises a wheel **63** which comprises female gear teeth **64**, illustrated in FIG. **21**, configured to cooperate with male gear teeth **65**, illustrated for example in FIG. **15**. The rotation of the wheel **63** thus results in the rotation of the body **40**. The moving system **52** comprises three second pins **66** secured to a piston **67** and engaged respectively in the three spiral ramps **59**, as illustrated in particular in FIGS. **11** and **17** to **19**. The piston **67** is secured to the needle holder **51** and it is mounted in sliding connection about the vertical axis **X5**. The rotation of the wheel **63** thus results in the rotation of the body **40** and, thus, the movement of the spiral ramps **59** with respect to the second pins **66**, then resulting in the translation along the vertical axis **X5** of the piston **67** and of the needle holder **51**, with respect to the element **62** of the frame **2**. With regard to the shape of the spiral ramps **59**, illustrated in particular in FIGS. **17** and **18**, a clockwise rotation of the wheel **63** results in a downward translation of the needle holder **51**, and vice versa in the counter-clockwise direction.

As illustrated in FIGS. **7** and **19**, a surface gasket **68** is arranged on the lower face of the needle holder **51**, said needles **53a**, **53b**, **53c** passing through said gasket **68**. When the needle holder **51** is in the engaged position on the pod **4**, this gasket **68** comes suitably into contact with the surface of the seal **57** of the pod **4**, which eliminates the venting of the storage chambers **55a**, **55b** and of the channel **56** of the pod **4** after this seal **57** is perforated by the needles **53a**, **53b**, **53c** and during the injection of fluids inside said pod **4**.

As illustrated in particular in FIGS. **17** and **18**, each spiral ramp **59** comprises three different slope zones **59a**, **59b**, **59c**. The first slope zone **59a** corresponds to a zone where the needles **53a**, **53b**, **53c** approach contact with the seal **57** of the pod **4**. The other slope zones **59b**, **59c** correspond to two phases of a work zone where the needles **53a**, **53b**, **53c** are engaged on the pod **4**. The slope zone **59b** corresponds to a first phase of penetration of the needles **53a**, **53b**, **53c** in the seal **57** of the pod **4** and the slope zone **59c** corresponds to a second phase of sealing of the pod **4** where the gasket **68** on the needle holder **51** suitably molds to the seal **57** after its perforation by said needles **53a**, **53b**, **53c**. In addition, each spiral ramp **59** comprises two protrusions **69a**, **69b** allowing the body **40** to be held in position with respect to the pin **66** in two extreme rotation positions, as long as manual action is not applied on the wheel **63**. This ensures that the needle holder **51** is stopped and suitably held in the engaged position and in the released position corresponding to said extreme positions. Preferably, the spiral ramps **59** are configured so that the pins **66** reach the extreme positions with respect to the body **40** by turning the wheel **63** through an angle between 50° and 90° , preferably 65° . Preferably, the moving system **52** comprises a spring (not illustrated) arranged between the piston **67** and the element **62** of the

frame 2, this spring making it possible to assist the lowering of the piston 67 in the phases of approach and perforation of the seal 57 of the pod 4.

The needles 53a, 53b, 53c each comprise a sharpening with three slopes 70a, 70b, 70c so that a point 71 can be formed at the extremity of each needle, which facilitates the perforation of the seal 57 with a reduced torque during the rotation of the wheel 63. For the same purpose, it is possible to provide for different lengths for the needles 53a, 53b, 53c, which makes it possible to sequence the contacts of said needles with the seal 57 of the pod 4 and, thus, to sequence the perforation efforts of said seal. Preferably, the two off-center needles 53a, 53c are of the same length for better stability during perforation of the seal 57.

As illustrated in particular in FIGS. 7, 15 and 21, the machine 1 comprises a system 72 for detecting the engaged position of the needles 53a, 53b, 53c on the seal 57 of the pod 4. This detection system 72 comprises a strip sensor-type switch 73, which is secured to the element 62 of the frame 2, and a protuberance 74 arranged inside the wheel 63. The needle holder 51 reaches the engaged position with respect to the pod 4 by turning the wheel 63 clockwise until the pins 66 surpass the protrusions 69b on the spiral ramps 59, in which position the protuberance 74 abuts against the switch 73 and activates it, which allows the machine 1 to initiate the cycle of dispensing fluids through the needles 53a, 53b, 53c ensuring a perfect sealing between the needle holder 51 and the pod 4 and, thus, proper dispensing of the beverage.

At the end of the beverage dispensing, the user turns the wheel 63 counter-clockwise until the pins 66 surpass the protrusions 69a on the spiral ramps 59, which allows the piston 67 and the needle holder 51 to rise. During this rise, the pod 4 could remain stuck to the needle holder 51, which could block the opening of the container 3. To guarantee that the pod 4 stays in the housing zone 33 of the container 3 during the release of the needles 53a, 53b, 53c, a stop element 75 on the frame 2 is positioned above a portion of the seal 57 of the pod 4 with the container 3 in the closed position, as illustrated by FIG. 19.

As illustrated in FIGS. 22 to 27, the pod 4 comprises a body 76 comprising an intermediate surface 77 and walls 78, 79 defining the two storage chambers 55a, 55b and the channel 56. The intermediate surface 77 is covered with a film (not represented in the figures) to close the two storage chambers 55a, 55b. The pod 4 also comprises a movable bottom 80 arranged in a sliding manner in the body 76, below the intermediate surface 77. The movable bottom comprises two needles 80a, 80b. During the placement of the needle holder 51 on the seal 57 of the pod 4, when the pins 66 are situated in the work zone on the spiral ramps 59, the movable bottom 80 slides in the body 76 of the pod 4 until it reaches the intermediate surface 77. The needles 80a, 80b perforate the film, which permits the activation of the pod 4 and the constitution of a mixing chamber (not illustrated). This mixing chamber communicates with the two chambers 55a, 55b and the channel 56, which allows the ingredients and the water inside this mixing chamber to be dispensed during the dispensing of fluids for the preparation of the beverage, which gradually flows through an outlet opening 81 arranged in the movable bottom 80. Other pod 4 designs may be envisioned, where the principle of moving the needle holder 51 from the released position to the engaged position on the pod 4 using the aforementioned moving system 52 remains identical.

When the container 3 is open for the placement of a pod 4 or the removal of a used pod 4, any movement of the

needle holder 51 toward the engaged position should be avoided, so that the container 3 does not strike the needle holder 51 during the next closing, which could damage the machine 1. For this reason, the machine 1 comprises a system 82 to block the moving system 52, illustrated with regard to FIGS. 3, 7, 11 and 15. The blocking system 82 comprises a blocking part 83 mounted in sliding connection with respect to the element 62 of the frame 2 such that it slides from a retracted position illustrated in FIG. 15 where the head 83a of the blocking part 83 is housed in the element 62 of the frame 2, to an active position illustrated in FIGS. 3 and 7 where the head 83a of the blocking part 83 surpasses the element 62 of the frame 2 and engages in an opening 84 arranged in the bottom of the wheel 63, which blocks the rotation of this wheel 63, thus preventing the activation of the moving system 52 which holds the needle holder 51 in a released position. The translation of the blocking part 83 is obtained by means of a circular groove 89 arranged on the container 3, this circular groove 89 comprising a curved bottom 90 in which is housed a foot 91 arranged at the lower extremity 83b of the blocking part 83. When the container 3 is pivoted to a closed position, the foot 91 is housed in the depression of the curved bottom 90, in the central part of the circular groove 89, as illustrated in FIGS. 10 and 11, in which position the head 83a of the blocking part is released from the opening 84. On the contrary, when the container 3 is in an open position by pivoting clockwise or counter-clockwise, the foot 91 is situated on one of the edges 89a, 89b of the circular groove 89, in the least deep portion of the curved bottom 90, in which position the head 83a is engaged in the opening 84.

When the needle holder 51 is engaged on the pod 4 for dispensing a beverage, any possibility of opening the container 3, which could also damage the machine 1, should be avoided. For this purpose, the machine 1 comprises a system 85 to deactivate the locking/unlocking system 18, preventing the lock 34 from being released from the housing 36 on the container 3. This deactivation system 85 is one or more by means of the control button 39 mounted in sliding connection with respect to the body 40 of the control member 58, said body being mounted such that it can rotate about the vertical axis X5. The finger 41 on the control button 39 is off-center with respect to the vertical axis X5. When the wheel 63 is in a position in which the pins 66 are abutting in the spiral ramps 59 at the protrusions 69a, the needle holder 51 is released from the pod 4 and the finger 41 corresponds with the upper extremity 37b of the connecting rod 37, as illustrated in FIGS. 8, 9 and 16, which allows the lock 34 to be unlocked by pressing on the control button 39 in order to open the container 3. As soon as the wheel 63 is turned and the pins 66 leave the protrusions 69a to move to the approach zone and the work zone on the spiral ramps 59, the finger 41 is released from the upper extremity 37b of the connecting rod 37, which prevents the activation of the connecting rod 37 and the release of the lock 34 when the control button 39 is pressed.

As illustrated in particular in FIGS. 1 to 4, the frame 2 of the machine 1 comprises a support foot 86 in the form of a cylindrical portion. The lower portion 3a of the container 3 comprises two flanges 87a, 87b which are positioned above the support foot 86 when said container 3 is in the closed position. During a movement of the needle holder 51 from the released position to the engaged position on the pod 4, these two flanges 87a, 87b bear against the support foot 86, which ensures load transfer during the engagement of the needle holder 51 on the pod 4.

11

As illustrated in particular in FIGS. 2 and 3, the container 3 comprises two recesses 88a, 88b arranged on each side of the receiving zone 33 of the pod 4, which facilitates the placement of the pod 4 in said receiving zone 33, and conversely its removal. For the same purpose, the slot 47

also facilitates the manipulation of the pod 4 during its positioning in the container 3 or its removal from the latter. The container 3 also comprises a support part (not illustrated) receiving the pod 4, this support part being configured to be removably housed in the receiving zone 33, in order to allow it to be removed and facilitate the cleaning of said container 3.

The machine 1 also comprises a reading system (not illustrated), for example a barcode reader, which is arranged on the frame 2 or on the second connecting rod 42, such that it is positioned opposite the slot 47 on the container 3 arranged in the closed position and such that it allows the reading of a graphic code arranged on the portion of the contour 48 of the pod 4 appearing at the slot 47. This allows the machine 1 to recognize the type of pod 4 arranged in the container 3 and the beverage to prepare, in order to control the dispensing of fluids accordingly. When the presence sensor 46 indicates the presence of a pod 4 in the container 3 in the closed position, and the switch 73 indicates that the needle holder 51 is in the engaged position on the pod 4, and the reading system has recognized the type of pod 4 arranged in the container, the activation management system (not illustrated) of the machine 1 controls the fluid-dispensing device in order to supply the quantities of fluids necessary to prepare the beverage. This reading system may also fulfill the function of the presence sensor 46, since the reading of the graphic code systematically indicates the presence of a pod 4 in the receiving zone 33 of the container 3.

The preceding description is not restrictive in nature, numerous variants being possible without departing from the context of the invention. For example, one could provide for implementation variants for the system 52 for moving the needle holder 51. For example, one could provide for a reversal of the direction of the ramps 59 on the body 40 of the control member 58, for the movement of the needle holder 51 from the released position to the engaged position on the pod 4, and vice versa. In this case, the direction of rotation of the wheel 63 will be reversed.

One could also provide for needles 53a, 53b, 53c having identical lengths and coming into contact simultaneously with the seal 57 of the pod 4.

One could also provide for a different number of needles, according to the type of pod 4 that may be used to prepare beverages.

In one embodiment, the machine 1 allows cold beverages to be prepared. However, one can envision embodiment variants for the preparation of hot beverages, the machine 1 being in this case equipped with a hot water production device heating the water prior to its dispensing.

The invention claimed is:

1. A machine for dispensing beverages from a pod, comprising a frame, a container including a pod-receiving zone, and an opening/closing device arranged between the frame and the container so as to pivot the container about a vertical axis between a closed position permitting the beverage to be dispensed and an open position permitting access to the pod-receiving zone, wherein the opening/closing device is configured such that the container has a 180° angular stroke for moving from the closed position to the open position and vice versa, such that a direction of rotation of the container can be clockwise or counter-clockwise, at the user's discretion, wherein the opening/closing device

12

includes an orientation system for orientation of the opening of the container, the orientation system being configured to open the container such that the container is constrained, by the orientation system, to open in a rotational direction about the pivot axis that is opposite to a rotational direction of the preceding closing.

2. The machine according to claim 1, wherein the opening/closing device includes an opening assistance system configured to bring the container from the closed position to the open position.

3. The machine according to claim 2, wherein the opening assistance system comprises a support member which cooperates with a plate secured to the container along the vertical axis, said plate comprising at least one ramp on which said support member rests, such that an effort applied by the support member on the at least one ramp results in the rotation of the plate in at least one direction about the vertical axis.

4. The machine according to claim 3, wherein the support member cooperates with a housing arranged on the plate to keep the container in the open position.

5. The machine according to claim 3, wherein the support member comprises a roller.

6. The machine according to claim 1, comprising a locking/unlocking system configured to keep the container in the closed position with respect to the frame and, conversely, to release the container so that the container is pivotable to the open position.

7. The machine according to claim 6, wherein the locking/unlocking system comprises, on the frame, a movable lock and a control system configured to control the lock and, on the container, a housing configured to receive the lock in the closed position.

8. The machine according to claim 7, wherein the control system comprises a connecting rod secured to the lock, a control button for the connecting rod and an element for returning the lock to the position maintaining the container.

9. The machine according to claim 6, comprising an impulsion system configured to force the container to pivot when the container is released by the locking/unlocking system.

10. The machine according to claim 1, comprising a load transfer system arranged between the frame and the container, configured to stabilize the container during operation of the machine.

11. The machine according to claim 10, wherein the load transfer system comprises at least one flange on the container and at least one support foot on the frame, said flange resting on said support foot in the closed position.

12. The machine according to claim 1, wherein the container comprises a gripping system configured to grip the pod in position in the pod-receiving zone.

13. The machine according to claim 1, wherein the container comprises a support part for the pod configured to be positioned in the pod-receiving zone and to receive said pod, said support part being removable.

14. A machine for dispensing beverages from a pod, comprising a frame, a container including a pod-receiving zone, and an opening/closing device arranged between the frame and the container so as to pivot the container about a vertical axis between a closed position permitting the beverage to be dispensed and an open position permitting access to the pod-receiving zone, wherein the opening/closing device is configured such that the container has a 180° angular stroke for moving from the closed position to the open position and vice versa, such that a direction of rotation of the container can be clockwise or counter-clockwise, at

13

the user's discretion, wherein the opening/closing device includes an orientation system for orientation of the opening of the container configured to open the container in the direction opposite to the direction of the preceding closing, and wherein the orientation system is configured to stop the container from pivoting when the container reaches the closed position, said orientation system including a stop arranged on the frame and a stopping member arranged on the container.

15. The machine according to claim 14, wherein the stopping member of the container comprises a vertical rib arranged along an axis of rotation of the container.

16. The machine according to claim 14, wherein the stop consists of a nose of a trigger able to move in rotation on either side of a middle position against two springs.

17. A machine for dispensing beverages from a pod, comprising:

- a frame;
- a container including a pod-receiving zone;
- an opening/closing device arranged between the frame and the container so as to pivot the container about a vertical axis between a closed position permitting the beverage to be dispensed and an open position permitting access to the pod-receiving zone, wherein the opening/closing device is configured such that the container has a 180° angular stroke for moving from the closed position to the open position and vice versa, such that a direction of rotation of the container can be clockwise or counter-clockwise, at the user's discretion, and
- a detection system configured to detect the presence of a pod in the container when said container is in the closed position.

14

18. The machine according to claim 17, wherein the container comprises a vertical slot communicating with the pod-receiving zone, the detection system comprising a presence sensor and a moving system configured to move the presence sensor to a position released from the slot during the initiation of the opening or closing of the container, or to a position engaged in the slot.

19. A machine for dispensing beverages from a pod, comprising:

- a frame;
- a container including a pod-receiving zone;
- an opening/closing device arranged between the frame and the container so as to pivot the container about a vertical axis between a closed position permitting the beverage to be dispensed and an open position permitting access to the pod-receiving zone, wherein the opening/closing device is configured such that the container has a 180° angular stroke for moving from the closed position to the open position and vice versa, such that a direction of rotation of the container can be clockwise or counter-clockwise, at the user's discretion, and
- a fluid-dispensing needle holder, a moving system for moving the needle holder from a position released from the pod to a position engaged on the pod, and a system for blocking the moving system, configured to keep the needle holder in the position released from the pod as long as the container has not returned to the closed position.
