## **ABSTRACT**

A system and method for disinfecting hard surfaces in an area such as a hospital room including a light source emitting UV light and a reflector mounted behind the light source for concentrating and directing the light toward a target. The light source and reflector rotate to direct the concentrated beam around a room, thereby making more efficient use of the energy being emitted.

## HARD SURFACE DISINFECTION SYSTEM AND METHOD

### RELATED APPLICATIONS

**[0001]** The present application is a divisional application from Australian Patent Application No. 2021204510, which is a divisional application from Australian Patent No. 2020294165, which is a divisional application from Australian Patent Application No. 2018236761, which is a divisional application from Australian Patent Application No. 2016259410, which is a divisional application from Australian Patent Application No. 2013214992, the entire disclosures of which are incorporated herein by reference. This application also claims priority to U.S. Provisional Application Serial No. 61/593,182 filed January 31, 2012, entitled Hard Surface Disinfection System And Method, which is hereby incorporated herein by reference in its entirety.

### BACKGROUND OF THE INVENTION

**[0002]** Contrary to the progress made in overall healthcare, the problems associated with health care-associated infections have grown steadily worse. Furthermore, the emergence of multi-drug resistant bacteria and spore “Super Bugs” and their presence in the hard surface environment are recognized as a significant threat in the transmission of infectious disease and associated mortality. Numerous scientifically peer-reviewed studies support the role of the environment in disease transmission. In recognition of this data, thorough disinfection of hard surfaces is an effective and evidence-based way to reduce the presence of these organisms that cause infections and mortality.

**[0003]** Published data reviewing the effectiveness of health care cleaning indicate that greater than 50% of patient room surfaces are not effectively cleaned and/or disinfected after a patient is discharged from the institution. Similar data reflect cleaning proficiency in non-health care environments. As a result, clinicians, health care personnel, visitors, and patients come in contact with bacteria or spores that remain in the room from a prior patient.

**[0004]** Introducing UV-C energy is an evidence-based way to manage the presence of bacteria and spore—including multi-drug resistant organisms. Disinfecting hard surfaces, such as those found in patient areas, can be performed by exposing the hard

surfaces to UVC energy that is harmful to micro-organisms such as bacteria, viruses, fungi and spore. Ultraviolet germicidal irradiation (UVGI) is proven sterilization method that uses ultraviolet (UV) energy at sufficiently short wavelengths to break-down and eradicate these organisms. It is believed that the short wavelength radiation destroys organisms at a micro-organic level. It is also believed that UV energy works by destroying the nucleic acids in these organisms, thereby causing a disruption in the organisms' DNA. Once the DNA (or RNA) chain is disrupted, the organisms are unable to cause infection.

**[0005]** In addition to the effectiveness described above, there are advantages to using UV-C energy alone or in concert with other disinfection modalities. UV-C requires only electricity; there is no off-gassing of chemicals frequently associated with chemical based products. In the event a room must be occupied immediately, the introduction of UV-C energy can be immediately terminated and the room immediately occupied. Alternative disinfection modalities, on the other hand, often result in lingering chemicals or agents that must be cleared from the room prior to entry. UV-C energy leaves no residue, does not require drying time, cannot be spilled, requires little manpower to apply, requires very little skill on the part of the operator, and uses long-lasting bulbs that require very little inventory management.

**[0006]** Using UV-C energy to disinfect hard surfaces does present some unique problems. For example, two primary challenges impact efficacy and energy delivery of UV-C energy: shadows and distance. UV-C emitters may not be able to eradicate bacteria in shadowed areas because the energy is delivered along a line-of-sight. Though reflected UV-C light may have some disinfecting ability, the amount of reflected energy depends on the surface from which the light is reflected and cannot be relied upon to adequately disinfect a shadowed area. As such, shadowed areas must be eliminated for effective disinfection. In addition, the UV-C emitting source may itself create shadows. As such, one must consider address these shadows for effective delivery of UV-C energy.

**[0007]** Second, the attempt to introduce UV-C energy to a space is dramatically impacted by the Inverse Square Law. This Law states that the intensity of the energy delivered to a surface is proportional to the inverse of the square of the distance between the energy source and the object. In other words, the energy received from the

UV emitting source decreases exponentially as the distance is increased. Thus, if one object is twice as far away from a light source as another object, the further object receives only one quarter the energy as the closer object. Knowing specific energy levels are required to eradicate specific organism, this can dramatically impact efficacy.

**[0008]** Third, UV light sources strong enough to kill bacteria can draw a substantial amount of electricity and generate heat.

**[0009]** As such, there is a need for a UV hard-surface disinfection system that exploits the advantages of UV energy, while also addressing the aforementioned problems.

**[0010]** More specifically, there is a need for a UV hard-surface disinfection system that maximizes the effectiveness of the energy being emitted from its bulbs while eliminating shadows and reaching all surfaces in a treated area despite fall-off due to distances from the light source(s).

**[0011]** A reference herein to a patent document or any other matter identified as prior art, is not to be taken as an admission that the document or other matter was known or that the information it contains was part of the common general knowledge as at the priority date of any of the claims.

#### SUMMARY OF THE INVENTION

**[0012]** One aspect provides a UV hard-surface disinfection system that may disinfect the hard surfaces in a room, while minimizing missed areas due to shadows. In one embodiment, a system is provided that includes multiple UV light towers. These towers may be placed in several areas of a room, or moved around during treatment, such that nearly all shadowed areas are eliminated.

**[0013]** Another aspect provides a UV hard-surface disinfection system that may maximize the efficacy of the light being emitted by including a reflector that focuses the light in a given direction, which may thereby ensure that enough light hits a surface to provide an effective bacteria killing dose, and also may increase the effective range of the UV bulbs.

**[0014]** Another aspect provides a UV hard-surface disinfection system that may include a motorized reflector that rotates around a bulb or bulbs, such that the light emitted from the lamps may not only be focused and concentrated, but may also be rotated around the room being treated, which may maximize the utility of the energy used and eliminate shadows that may be created by the device itself.

**[0015]** Another aspect provides a cooling fan that may be used to cool the UV bulbs, which may thereby increase the life of the bulbs and manage optimal temperature for optimal output.

**[0016]** In yet another aspect there is provided a UV disinfection system that may minimize UV light exposure to humans during operation. In a preferred embodiment, the system is able to be controlled remotely, such that during activation of the system, no operator is present in the room.

**[0017]** Another aspect provides a system in which one or all towers may be outfitted with safety devices that cut power to all towers in the event that a person enters the room. More preferably, the safety device includes motion-detecting capability, such that the safety shutdown response is automatic. Examples of motion-detection sensors may include infra-red sensor and laser scanners.

**[0018]** Another aspect provides a linking connector that may be constructed and arranged to join two towers together. Multiple linking connectors may be used to create a train of towers used to transport a plurality of towers. The advantage of this linkage connector is the UV-C emitters may be easily moved from each desired treatment area while maintaining critical hallway egress to ensure building codes are not breached by the presence of other equipment. The connector may be operated and positioned easily by a single operator. Alternatively, the towers may be linked together with the connector to form a chain. This embodiment may allow the towers to support themselves continuously, while being transported by pushing or pulling the emitters. This embodiment may allow the use of a hand-cart attachment, which may provide a solution to moving all of the units from one room to another without requiring that they be moved individually.

**[0019]** Another aspect provides a scanning system that may scan a room to be treated and determine how long the system must be energized in order to effectively treat the room.

**[0020]** Another aspect provides a system whereby multiple towers may detect each other and their respective locations in a room, as well as other objects, and the towers may then use this information to compute exposure times that are inversely proportional to these distances.

**[0021]** Another aspect provides an algorithm that may adjust the speed of rotation of a reflector/lamp combination to achieve desired energy densities on room surfaces. This differential rotation of the lamp/reflector pair may allow towers to normalize exposure on room surfaces, which may thereby ensure that all surfaces achieve approximately equal exposure. This may result in minimum total exposure times to treat a room or an area of a room. The algorithm may further factor the locations of other towers and the energy those towers are contributing to the energy falling into any given area in the room. The exposure times may then be adjusted for each tower to account for the additive exposure from multiple towers to result in a minimized exposure time used to sanitize the room.

**[0022]** A device for disinfecting an area is described herein comprising: a base assembly; at least one emitter of energy attached to said base assembly; a reflector proximally associated with said emitter; wherein said reflector directs energy from said emitter onto an area to be disinfected; and a motor configured to rotate said reflector relative to said base assembly.

**[0023]** In one embodiment, the base assembly comprises a fan.

**[0024]** In this or another embodiment, the base assembly comprises said motor.

**[0025]** In this or another embodiment, the at least one emitter of energy comprises at least one emitter of ultraviolet light.

**[0026]** In this or another embodiment, the at least one emitter of ultraviolet light comprises at least one UV-C lamp.

**[0027]** In this or another embodiment, the base assembly comprises an antenna usable to establish communication with a remote control device.

**[0028]** In this or another embodiment, the antenna comprises an antenna useable for communication using Bluetooth® wireless technology.

**[0029]** In this or another embodiment, the reflector comprises a parabolic reflector.

**[0030]** A method of disinfecting a designated area is also described herein comprising: placing at least one emitter of energy in a room, said emitter configured to emit disinfecting energy in a form of a beam; rotating said beam in a circle until a desired amount of energy has been delivered to surfaces in said room.

**[0031]** In this or another embodiment, the method further comprises controlling a rate at which said beam rotates based on distances measured from said emitter to various objects to be disinfected in said room.

**[0032]** In this or another embodiment, placing at least one emitter of energy in a room comprises placing a plurality of emitters of energy in a room.

**[0033]** In this or another embodiment, controlling rates at which beams of each of said plurality of emitters rotate based on distances measured from said emitters to various objects to be disinfected in said room.

**[0034]** In this or another embodiment, controlling rates at which beams of each of said plurality of emitters rotate is further based on distances measured between said plurality of emitters.

**[0035]** A system for disinfecting an area is also described herein comprising: a plurality of devices, each comprising: a base assembly; at least one emitter of energy attached to said base assembly; a reflector proximally associated with said emitter; wherein said reflector directs energy from said emitter onto an area to be disinfected; and a motor configured to rotate said reflector relative to said base assembly.

**[0036]** In this or another embodiment each of said plurality of devices further comprises a sensor usable to determine distances to objects surrounding said device.

**[0037]** In this or another embodiment each of said plurality of devices further comprises a sensor usable to determine distances to other of said plurality of devices.

**[0038]** In this or another embodiment the system further comprises link connectors usable to join two of said plurality of devices together.

**[0039]** In this or another embodiment each of said plurality of devices comprises an electronic control circuit that controls a rate of rotation of said reflector via said motor.

**[0040]** In this or another embodiment said rate of rotation is calculated based on locations of other of said plurality of said devices.

**[0041]** In this or another embodiment each of said plurality of said devices comprises an antenna usable to communication with a remote controller for receiving instructions therefrom.

#### BRIEF DESCRIPTION OF THE FIGURES

**[0042]** Figure 1a is a perspective view of an embodiment of the present invention;

**[0043]** Figure 1b is an elevation view of an embodiment of the present invention;

**[0044]** Figure 1c is a side view of an embodiment of the present invention;

**[0045]** Figure 2 is a perspective view of a base of an embodiment of the present invention with a cover removed;

**[0046]** Figure 3 is a perspective view of a base of an embodiment of the present invention with some components removed to show inner components;

**[0047]** Figure 4 is a perspective view of a reflector motor of an embodiment of the present invention;

**[0048]** Figures 5 is a perspective views of an upper portion of an embodiment of the present invention;

**[0049]** Figure 6 is a perspective view of an upper portion of an embodiment of the present invention;

**[0050]** Figure 7 is a perspective view of three devices of the invention connected together to form a chain of devices for transport purposes.

#### DESCRIPTION OF EMBODIMENTS

**[0051]** Specific embodiments of the invention will now be described with reference to the accompanying drawings. This invention may, however, be embodied in many different forms and should not be construed as limited to the embodiments set forth herein; rather, these embodiments are provided so that this disclosure will be thorough and complete, and will fully convey the scope of the invention to those skilled in the art. The terminology used in the detailed description of the embodiments illustrated in the accompanying drawings is not intended to be limiting of the invention. In the drawings, like numbers refer to like elements.

**[0052]** Referring now to Figures 1a – c, there is shown an embodiment of a device 100 of the invention. Device 100 is a light tower that generally includes a base assembly 110, a lamp assembly 150, a cap assembly 200, and a hand rail 250. The device 100 is configured for use with a computer application for controlling one or more devices. The application is downloadable and useable on a portable device such as a smart phone or tablet. It is to be understood that in use, it is possible to use several devices 100 simultaneously in order to treat an area large enough to merit the use of more than one device 100.

**[0053]** Referring now to Figure 2, there is shown an embodiment of a base assembly 110 of the invention. Beginning at the bottom of the base assembly 110, the device 100 includes at least three, preferably four or more wheels 112. The wheels 112 are preferably mounted on swiveling casters such that the device 100 may be moved easily from room to room during a cleaning operation. The wheels are mounted on a base housing 114, which includes a removable panel 116, shown in Figure 1 but removed in Figure 2 to show the parts contained therein.

**[0054]** In an alternate embodiment, wheels 112 are powered and directed by a drive unit (not shown) such as a motor. The motor is either controlled remotely by an operator or locally by an onboard navigation system. It is contemplated that the scanning system (discussed below) provides navigational input to the navigation

system, allowing the device 100 to move around the room during the disinfection process in a computed manner calculated to eliminate shadow areas.

**[0055]** An aperture in the removable panel 116 is provided to expose an antenna 118, useable to communicate with a device, such as a smartphone, utilizing the control application. The antenna 118 may be configured to support any wireless communication technology such as IR, radio waves, WLAN, Wi-Fi, or Bluetooth®. Wireless is preferred to tethered as the device 100 is preferably operated in a room without human presence, as UV radiation can be harmful to humans. The antenna 118 is in data-flow communication with a control circuit 119.

**[0056]** Just above the antenna 118 is a portal 120 for a retractable cord 122 (see Figure 1). The cord 122 may be collected on a spring-loaded, ratcheting spool below the portal 120.

**[0057]** Also below the portal, centered in the bottom of the base assembly, is a fan 124. Fan 124 works in conjunction with a fan in the cap assembly 200 (discussed below), to create a steady stream of cooling air through the lamp assembly 150.

**[0058]** Figure 3 shows the base assembly 110 with some of the components removed so that the electronic control circuit board 130 and the lamp ballasts 132 are shown. The control circuit board 130 runs an algorithm that allows multiple devices 100 to detect each other and their respective locations in a room, as well as other objects, and the control circuit board 130 then uses this information to compute exposure times that are inversely proportional to these distances.

**[0059]** The control circuit board 130 also controls motor 154 (discussed below) to adjust the speed of rotation of the lamp assembly 150 to achieve desired energy densities on room surfaces. This differential rotation of the lamp assembly 150 allows devices 100 to normalize exposure on room surfaces, thereby ensuring that all surfaces achieve approximately equal exposure. This results in minimum total exposure times to treat a room or an area of a room. The algorithms run by the circuit board 130 further factor the locations of other devices 100 and the energy those devices 100 are contributing to the energy falling into any given area in the room. The exposure times are then adjusted for each device 100 to account for the additive exposure from multiple towers to result in a minimized exposure time used to sanitize the room.

**[0060]** The base assembly 110 is attached to the lamp assembly 150 with a swivel connector 152, best shown in Figure 4. The swivel connector 152 allows the lamp assembly 150 to rotate in relation to the base assembly 110. A motor 154 is mounted on the base assembly 110 and attached via a drive mechanism 156 to the lamp assembly 150, such that the motor 154, when activated, causes rotation of the lamp assembly 150 relative to the base assembly 110. The drive mechanism 156 is shown as a belt-drive in Figure 4, but one skilled in the art would recognize that motors can be configured to drive objects using gears, belts, chains, worm-drives, or other mechanisms, all considered to be included as embodiments of the invention.

**[0061]** The lamp assembly 150 also includes at least one lamp 160, as seen in Figure 5. The number of lamps 160 may be determined by the intended application and desired bulbs available. The embodiment shown in Figure 5 shows three lamps 160. In one or more embodiments of the invention, the lamps emit UV-C light. Though the lamps 160 shown utilize existing fluorescent UV-C technology, one skilled in the art will realize that advancements in UV-C lamps could result in a variety of lamps being used with the invention.

**[0062]** Behind the lamps 160 is a reflector 162. The reflector 162 wraps around the lamps 160 in order to focus and concentrate the light emitted from the lamps 160 in a desired direction. The reflector 162 may be parabolic, catenary, semi-circular, circular, or other curves, depending on the desired reflective result and/or the placement of the lamps. For example, a parabolic reflector, with the lamps located approximately close to the parabolic focal point, would result in a relatively narrow, focused (collimated) beam. Such a beam increases the intensity of UV radiation in a desired direction.

**[0063]** If desired, it is possible to incorporate a flatter reflector, such as a semi-sphere or catenary reflector. In this regard, a flexible reflector 162 may be provided that is connected to the device 100 in a manner that allows the curve of the reflector to be adjusted based on the desired application.

**[0064]** Alternatively, beam adjustment or focusing could be accomplished by adjusting the lamp position relative to the reflector to create a “zoom” function that would allow the beam to be either more or less tightly focused.

**[0065]** At the bottom of the lamp assembly 150, a lower planar reflector 164 (Figure 2) is optionally provided. The planar reflector 164 may be angled downwardly, as shown, to scavenge the UV energy that would otherwise be directed onto the floor, where disinfection is typically less critical, and direct it upward into higher areas of the room.

**[0066]** Similarly, at the top of the lamp assembly 150, is an upper planar reflector 166 (Figure 5). The upper planar reflector 166, like the lower planar reflector 150, is angled to scavenge the UV energy that would otherwise be directed at the ceiling onto areas where human contact is more likely. The upper planar reflector 166 also includes an aperture 170.

**[0067]** Referring now to Figure 6, there is shown the cap assembly 200 of the invention. The cap assembly is oriented on top of the lamp assembly 150 and includes a sensor mechanism 210 and a cooling mechanism 220.

**[0068]** The sensor mechanism 210 includes a sensor 212 and a sensor drive mechanism 214. The sensor 212 may be any suitable sensor mechanism. Non-limiting examples include laser sensors, and IR (infra-red) sensors. The sensor 212 is used to scan the room to analyze distances to various surfaces and provide input as to the location of objects in the room. The data provided by the sensor 212 may be used to calculate potential shadow areas as well as necessary treatment times and powers. The sensor 212 may also include a motion detection capability, which detects movement prior to the activation of the devices 100 and aborts the treatment initiation in the event that motion is detected just before the treatment. Sensor 212 is shown in Figure 6 as a single sensor. However, the sensor 212 may incorporate multiple sensing modalities.

**[0069]** The embodiment shown in Figure 6 also includes a sensor drive mechanism 214. The sensor drive mechanism 214 attaches the sensor 212 to the cap assembly 200 and moves the sensor 212 up and down through the aperture 170 of the upper planar reflector 166.

**[0070]** The cap assembly 200 also includes a cooling mechanism 220 in the form of a fan. The cooling mechanism 220, when energized, creates airflow around the lamps 160 to draw heat away from them.

**[0071]** Figure 7 shows three devices 100 connected together with linking connectors 300. Linking connectors 300 include a base 302 and a handle 304. The bases 302 are shaped to be placed over two adjacent casters 112, on either side of the devices 100, totaling four casters, to lock two devices 100 together. The handle 304 provides a place to grab and lift the connector 300 and set it down over the casters 112. Using the linking connectors 300, a chain of devices 100 can be formed, allowing a single person to move multiple devices 100 easily.

**[0072]** Although the invention has been described in terms of particular embodiments and applications, one of ordinary skill in the art, in light of this teaching, can generate additional embodiments and modifications without departing from the spirit of or exceeding the scope of the claimed invention. For example, the device 100 described above includes a lamp assembly 150 that rotates relative to the base assembly 110. However, one skilled in the art would realize that the lamps 160 could be fixed relative to the base assembly 110 and the reflector 162 could be configured to rotate around the lamps 160. Accordingly, it is to be understood that the drawings and descriptions herein are proffered by way of example to facilitate comprehension of the invention and should not be construed to limit the scope thereof.

**[0073]** Where any or all of the terms "comprise", "comprises", "comprised" or "comprising" are used in this specification (including the claims) they are to be interpreted as specifying the presence of the stated features, integers, steps or components, but not precluding the presence of one or more other features, integers, steps or components.

The claims defining the invention are as follows:

1. A device for disinfecting an area comprising:  
a base assembly;  
at least one emitter of energy attached to said base assembly;  
a reflector proximally associated with said emitter;  
wherein said reflector directs energy from said emitter onto an area to be disinfected; and  
a motor configured to rotate said reflector relative to said base assembly.
2. The device of claim 1 wherein said base assembly comprises a fan.
3. The device of claim 1 wherein said base assembly comprises said motor.
4. The device of claim 1 wherein said at least one emitter of energy comprises at least one emitter of ultraviolet light.
5. The device of claim 4 wherein said at least one emitter of ultraviolet light comprises at least one UV-C lamp.
6. The device of claim 1 wherein said base assembly comprises an antenna usable to establish communication with a remote control device.
7. The device of claim 6 wherein said antenna comprises an antenna useable for communication using Bluetooth® wireless technology.
8. The device of claim 1 wherein said reflector comprises a parabolic reflector.
9. A method of disinfecting a designated area comprising:  
placing at least one emitter of energy in a room, said emitter configured to emit disinfecting energy in a form of a beam;  
rotating said beam in a circle until a desired amount of energy has been delivered to surfaces in said room.

10. The method of claim 9 further comprising controlling a rate at which said beam rotates based on distances measured from said emitter to various objects to be disinfected in said room.
11. The method of claim 9 wherein placing at least one emitter of energy in a room comprises placing a plurality of emitters of energy in a room.
12. The method of claim 11 further comprising controlling rates at which beams of each of said plurality of emitters rotate based on distances measured from said emitters to various objects to be disinfected in said room.
13. The method of claim 12 wherein controlling rates at which beams of each of said plurality of emitters rotate is further based on distances measured between said plurality of emitters.
14. A system for disinfecting an area comprising:
  - a plurality of devices, each comprising:
    - a base assembly;
    - at least one emitter of energy attached to said base assembly;
    - a reflector proximally associated with said emitter;
    - wherein said reflector directs energy from said emitter onto an area to be disinfected; and
    - a motor configured to rotate said reflector relative to said base assembly.
15. The system of claim 14 wherein each of said plurality of devices further comprises a sensor usable to determine distances to objects surrounding said device.
16. The system of claim 14 wherein each of said plurality of devices further comprises a sensor usable to determine distances to other of said plurality of devices.
17. The system of claim 14 further comprising link connectors usable to join two of said plurality of devices together.

18. The system of claim 14 wherein each of said plurality of devices comprises an electronic control circuit that controls a rate of rotation of said reflector via said motor.

19. The system of claim 18 wherein said rate of rotation is calculated based on locations of other of said plurality of said devices.

20. The system of claim 14 wherein each of said plurality of said devices comprises an antenna usable to communication with a remote controller for receiving instructions therefrom.
