(57) **ABSTRACT**

Computer-implemented techniques for multi-modal aquatic biomass estimation includes determining a fish mass measurement, a fish count, or a direct fish biomass estimate from a sample of one or more digital images or digital video captured by a digital camera immersed underwater in a fish farm enclosure. A technique further includes determining a plurality of fish densities for a plurality of water volumes within the fish farm enclosure based on analysis of signals received from a plurality of bias estimation sensors immersed underwater in the fish farm enclosure. The technique also includes computing a bias-adjusted fish mass measurement, fish count, or direct fish biomass estimate for the fish farm enclosure based on (i) the fish mass measurement, the fish count, or the direct fish biomass estimate determined from the sample of one or more digital images or digital video captured by the digital camera immersed underwater in the fish farm enclosure and (ii) the plurality of fish densities determined for the plurality of water volumes.

MULTI-MODAL AQUATIC BIOMASS ESTIMATION

BACKGROUND

[0001] The disclosed subject matter relates to computer-implemented techniques for multi-modal aquatic biomass estimation.

[0002] Aquaculture is the farming of aquatic organisms (e.g., fish) in both coastal and inland areas involving interventions in the rearing process to enhance production. Aquaculture has experienced dramatic growth in recent years. The United Nations Food and Agriculture Organization has estimated that aquaculture accounts for at least half of the world's fish that is used for food.

[0003] The rise of aquaculture has fostered interest in techniques that improve the production processes in fish farms. Along the same lines, there is interest in fish biomass estimation techniques that can help fish farmers optimize feeding, control stocking densities, and determine the optimal time to harvest.

[0004] Traditional techniques to estimate fish biomass involve manual sampling and weighing, which is often invasive, time consuming, and labor-intensive. Thus, less invasive, more efficient, and more cost-effective techniques are desired.

[0005] The approaches described in this section are approaches that could be pursued, but not necessarily approaches that have been previously conceived or pursued. Therefore, unless otherwise indicated, it should not be assumed that any of the approaches described in this section qualify as prior art merely by virtue of their inclusion in this section.

BRIEF DESCRIPTION OF DRAWINGS

[0006] Various embodiments in accordance with the present disclosure will be described with reference to the drawings, in which:

[0007] FIG. 1 depicts a computer vision-based aquatic biomass estimation system according to some embodiments.

[0008] FIG. 2 depicts the computer vision-based aquatic biomass estimation system of FIG. 1 with the addition of a bias estimation system according to some embodiments.

[0009] FIG. 3 depicts use of an active acoustic sensor for bias adjustment according to some embodiments.

[0010] FIG. 4 is a block diagram illustrating an example computer system that can be used in some embodiments.

DETAILED DESCRIPTION

[0011] The disclosed techniques for multi-modal aquatic biomass estimation encompass a method implementation, a non-transitory storage medium implementation, and a computer system implementation.

[0012] In one implementation of the disclosed techniques, the method for multi-modal aquatic biomass estimation is performed by one or more computing devices. The performance of the method by the one or more computing devices includes the step of determining a fish mass measurement, a fish count, or a direct fish biomass estimate from a sample of one or more digital images or digital video captured by a digital camera immersed underwater in a fish farm enclosure. The method further includes the step of determining a plurality of fish densities for a plurality of water volumes within the fish farm enclosure based on analysis of signals received from a plurality of bias estimation sensors immersed underwater in the fish farm enclosure. The method also includes the step of computing a bias-adjusted fish mass measurement, fish count, or direct fish biomass estimate for the fish farm enclosure based on (i) the fish mass measurement, the fish count, or the direct fish biomass estimate determined from the sample of one or more digital images or digital video captured by the digital camera immersed underwater in the fish farm enclosure and (ii) the plurality of fish densities determined for the plurality of water volumes.

[0013] In one implementation of the disclosed techniques, the non-transitory storage medium for multi-modal aquatic biomass estimation stores instructions which, when executed by one or more computing devices, cause the one or more computing devices to perform the above method for multi-modal aquatic biomass estimation.

[0014] In one implementation of the disclosed techniques, the computer system for multi-modal aquatic biomass estimation includes one or more hardware processors, storage media, and instructions stored in the storage media which, when executed by the one or more hardware processors, cause the one or more hardware processors to perform the above-method for multi-modal aquatic biomass estimation.

[0015] These and other implementations, as well as the disclosed techniques generally, are described in greater detail below with reference to drawings.

[0016] The disclosed techniques for multi-modal aquatic biomass estimation include using a computer vision-based fish biomass estimation system ("biomass estimation system"), a bias estimation system, and an extrapolation system. While the biomass estimation system, the bias estimation system, and the extrapolation system are described and depicted variously herein as being implemented using the same computer system (e.g., the same one or more computing devices), there is no requirement that this be the case. Instead, each can be implemented using a separate computer system.

[0017] FIG. 1 depicts a computer vision-based aquatic biomass estimation system 100. A monocular or stereo vision camera 102 is immersed under the water surface 104 in a fish farm enclosure 106. Camera 102 uses visible light to capture images or video of fish swimming freely in enclosure 106. The captured images or video provide pixel information from which quantitative information is extracted and analyzed for object recognition.

[0018] No type or configuration of camera 102 is required. In a possible implementation, camera 102 is an approximately 12-megapixel color or monochrome camera with a resolution of approximately 4096 pixels by 3000 pixels, and a frame rate of 1 to 8 frames per second. Although different cameras with different capabilities can be used according to the requirements of the implementation at hand. The lens or lenses or camera 102 can be selected based on an appropriate baseline and focal length to capture images of fish swimming in front of camera 102 in enclosure 106 where fish are close enough to the lens(es) for proper pixel resolution and feature detection in the captured image, but far enough away from the lens or lenses such that the fish can fit entirely in the image or video frame. For example, an 8-millimeter focal length lens with high line pair count (1 p/mm) can be used such that the pixels can be resolved. The baseline of

camera **102** can have greater variance such as, for example, within the range of 6 to 12-millimeter baseline.

[0019] Enclosure **106** can be framed by a plastic or steel cage that provides a substantially conical, cubic, cylindrical, spherical, or hemispherical shape. Enclosure **106** can hold several fish of a particular type (e.g., Atlantic salmon) depending on various factors such as the size of enclosure **106** and the maximum stocking density of the particular fish. For example, an enclosure **106** for Atlantic salmon can be 50 meters in diameter, 20-50 meters deep, and hold up to approximately 200,000 salmon assuming a maximum stocking density of 10 to 25 kg/m3. While enclosure **106** can be a net pen or sea-cage located in the open sea or open water, enclosure **106** can be a fish farm pond, tank, or other fish farm enclosure.

[0020] Camera **102** can be attached to winch system **116**. Winch **116** allows camera **102** to be relocated underwater in enclosure **106**. This allows camera **102** to capture images or video of fish from different locations within enclosure **106**. For example, winch **116** can allow camera **102** to move around the perimeter of enclosure **106** and at various depths within enclosure **106**. Winch **116** system can also allow control of pan and tilt of camera **102**. Winch **116** can be operated manually by a human controller such as, for example, by directing user input to a winch control system located above water surface **104**.

[0021] Winch **116** can operate autonomously according to a winch control program configured to adjust the location of camera **102** within enclosure **106**. The autonomous winch control system can adjust the location of camera **102** according to a series of predefined or preprogrammed adjustments or according to detected signals in enclosure **102** that indicate better or more optimal locations within enclosure **106** for capturing images or video of fish relative a current position or orientation of camera **102**. A variety of signals can be used such as, for example, machine learning and computer visions techniques applied to images or video captured by camera **102** to detect schools or clusters of fish currently distant from camera **102** such that a location that is closer to the school or cluster can be determined and the location, tilt, or pan of camera **102** adjusted to capture more suitable images of the fish. The same techniques can be used to automatically determine that camera **102** should remain or linger in a current location or orientation because camera **102** is currently in a good position to capture suitable images of fish. Instead of using winch **116** to position camera **102** within enclosure **106**, the housing of camera **102** can include underwater propulsion mechanisms such as propellers or water jets. In this case, camera **102** can move within enclosure **106** autonomously as in a self-driving fashion. Also in this case, camera **102** can include components and software to control autonomous navigation such as underwater LiDAR and computer vision-software.

[0022] While camera **102** can operate using natural light (sunlight), an ambient lighting apparatus can be attached to camera **102** or otherwise located within enclosure **106**. For example, the light apparatus can illuminate a volume of water in front of camera **102** lens(es) with ambient lighting in the blue-green spectrum (450 nanometers to 570 nanometers). This spectrum can be used to increase the length of the daily sample period during which useful images of fish in enclosure **106** can be captured. For example, depending on the current season (e.g., winter), time of day (e.g., sunrise or sunset), and latitude of enclosure **106**, only a

few hours during the middle of the day can be suitable for capturing useful images without using ambient lighting. This daily period can be extended with ambient lighting. Use of fluorescent, LED, or other artificial lighting is also possible.

[0023] Although not shown in FIG. **1**, a mechanical feed system that is connected by physical pipes to enclosure **106** can be present in the aquaculture environment. The feed system can deliver food pellets via the pipes in doses to the fish in enclosure **106**. The feed system can include other components such as a feed blower connected to an air cooler which is connected to an air controller and a feed dose-r which is connected to a feed selector that is connected to the pipes to enclosure **106**. The fish biomass estimates generated according to the disclosed techniques can be used as input to the feed system for determining the correct amount of feed in terms of dosage amounts and dosage frequency, thereby improving the operation of the feed system.

[0024] As well as being useful for determining the correct amount of feed, the fish biomass estimates generated according to the disclosed techniques are also useful for determining more optimal feed formulation. Feed formulation includes determining the ratio of fat, protein, and other nutrients in the food pellets fed to the fish in enclosure **106**. Using accurate biomass estimates generated by the disclosed techniques for fish in a particular enclosure, precise feed formulations for the fish in that enclosure can be determined. In this way, it is also possible to have different formulations for the fish in different enclosures based on the different biomass estimates determined by the disclosed techniques for those enclosures.

[0025] In addition to being useful for feed dosage optimization and feed formulation optimization, the accurate biomass estimates generated according to the disclosed techniques are also useful for determining optimal harvest times and maximizing sale profit for fish farmers. For example, fish farmers can use the biomass estimates to determine how much of different fish sizes they can harvest and bring to market. For example, the different fish sizes can be distinguished in the market by 1-kilogram increments. Thus, accurate biomass estimates are important to fish farmers to accurately determine which market bucket (e.g., the 4 kg to 5 kg bucket, the 5 kg to 6 kg bucket, etc.) the fish in enclosure **106** belong to. Having accurate biomass estimates also improves fish farmers' relationships downstream in the market such as with slaughterhouse operators and fish futures markets. Along the same lines, an accurate fish biomass estimate is useful for compliance with governmental regulations. For example, in Norway, a salmon farming license can impose a metric ton limit. Biomass estimates generated according to the disclosed techniques can be useful for ensuring compliance with such licenses.

[0026] System **100** includes various functional modules including image acquisition **108**, image processing **110**, and statistical analysis **112**. Digital images or video captured by camera **102** are sent via data communication channel **114** to system **100**. Data communication channel **114** can be a wired or wireless data communication channel. For example, data communication channel **114** can be a wired fiber data communication channel or a wireless data communication channel such as one based on a wireless data communication standard such as, for example, a satellite data com-

3

munication standard or a standard in the IEEE 802.11 family of wireless standards.

[0027] It is also possible for system **100** to be a component of camera **102**. In this case, data communication channel **114** is not needed to connect camera **102** to system **100**. Instead, data communication channel **114** can be used to connect camera **102** to another system (not shown) that processes the results produced by system **100**.

[0028] Regardless of if data communication channel **114** is used to convey images, video, or results produced by system **100**, the results produced by system **100** can be provided to another system such as, for example, a web application system that provides a web browser-based or a mobile phone-based graphical user interface at client computing devices. The graphical user interface can visually present the results produced by system **100** or information derived therefrom such as in a web dashboard or the like. The results produced by system **100** or the information derived therefrom presented in the graphical user interface can include a measurement of the mass of fish in enclosure **106** ("fish mass measurement"), a count of fish in enclosure **106** ("fish count"), or a direct estimate of the biomass of fish in enclosure **106** ("direct fish biomass estimate").

[0029] Image acquisition **108** includes receiving the images or video captured by camera **102** and storing the images or video on a storage media (e.g., storage media of system **100**) for further processing by image processing **110** and statistical analysis **112**. Image acquisition **108** can perform some basic filtering of images or video such as discarding unusable images or video such as, for example, images or video frames that do not appear to contain any aquatic organisms or are of poor quality because of inadequate lighting or because camera **102** was in motion when the images or video was captured resulting in blurry images or video.

[0030] Image acquisition **108** can also perform cataloging of the images and video captured by camera **102**. Cataloging can include associating captured images or video with metadata reflecting the situation or environment in enclosure **106** in which or at the time the images or video were captured by camera **102**. Image acquisition **108** can associate captured images or video with metadata in storage media (e.g., storage media of system **100**). Such metadata can include, but is not limited to, dates and times of when associated images or video were captured by camera **102** and position information for camera **102** when associated images or video were captured. The dates and times can be provided by a clock either of camera **102** or system **100**. The position information can be provided by a global positioning satellite sensor affixed to camera **102**, provided by camera winch system **116**, or provided by an accelerator sensor of camera **102** such as, for example, a microelectromechanical system sensor (MEMS).

[0031] However provided, the position information can indicate the position of camera **102** underwater in enclosure **106** in one or more spatial dimensions. The position information can indicate the position of camera **102** in the volume of water within enclosure **106**. For example, the position information can indicate one or more coordinates in a first plane and a coordinate in a second plane that is perpendicular to the first plane. For example, the first plane can be parallel to water surface **104**. The position information, then, can indicate an x-axis coordinate and a y-axis coordinate in the first plane and a z-axis coordinate in the second plane. For example, the x-axis coordinate, and

the y-axis coordinate can correspond to the position of camera **102** at water surface **104** and the z-axis coordinate can correspond to the depth of camera **102** underwater at the position of camera **102** at water surface **104** corresponding to the x-axis coordinate and the y-axis coordinate. In this example, the position of camera **102** within enclosure **106** is controllable by camera winch **116** in all three dimensions x, y, and z. However, camera winch **116** can allow positioning of camera **102** within enclosure **106** in just one or two of those dimensions. In this case, the dimension or dimensions that are not controllable by winch **116** can be fixed or otherwise predetermined.

[0032] The position information can also indicate the imaging orientation of camera **102** within enclosure **106**. In particular, the position information can indicate the direction of the lens of camera **102** when images or video associated with the position information were captured. For example, the position information can indicate a compass heading or an angular position. Here, the compass heading or angular position can be with respect to a plane parallel with the imaging direction of the lens where the imaging direction of the lens is perpendicular to the plane of the lens. For example, in system **100**, imaging direction **118** of lens of camera **102** is depicted as substantially parallel to water surface **104**. However, imaging direction **118** of lens of camera **102** can instead be substantially perpendicular to water surface **104** such as, for example, if camera **102** is positioned nearer to the bottom of enclosure **106** and imaging direction **118** is towards water surface **104** or if camera **102** is positioned nearer to water surface **104** and imaging direction **118** is towards the bottom of enclosure **106**.

[0033] The position information can also indicate a pitch angle of imaging direction **118** relative to a plane parallel to water surface **104** or relative to a plane perpendicular to water surface **104**. For example, the pitch angle of imaging direction **118** as depicted in FIG. **1** can be zero degrees relative to a plane parallel to water surface **104** or ninety degrees relative to a plane perpendicular to water surface **104**. Depending on the pitch of image direction **118**, the pitch angle can range between -90 degrees and +90 degrees or equivalently between 0 and 180 degrees.

[0034] Reference herein to the "position" of camera **102** can encompass any one of the following or a combination two or more thereof: an x-axis position of camera **102**, a y-axis position of camera **102**, a z-axis position of camera **102**, a compass heading of imaging direction **118** of camera **102**, an angular position of imaging direction **118** of camera **102**, a pitch angle of imaging direction **118** of camera **102**, a longitudinal position of camera **102**, a latitudinal position of camera **102**, an elevation of camera **102**, or a underwater depth of camera **102**.

[0035] The volumetric size of enclosure **106** and the number of fish in enclosure **106** can be such that, at a given position in enclosure **106**, camera **102** cannot capture sufficiently high-quality images or video of all the fish in enclosure **106** for use by system **100** to accurately estimate a fish mass measurement, a fish count, or a direct fish biomass estimate of all of the fish in enclosure **106**. Characteristics of the lens or lenses of camera **102** and the particular requirements of the imaging application at hand such as focal length, aperture, maximum aperture, and depth of field can limit the volume of water within enclosure **106** of which camera **102** at a given position can capture sufficiently high-quality images or video. As a result, the images

or video captured by camera **102** at a given position can be only a sample **120** of all fish in enclosure **106**. As used herein, a "sample" as in, for example, sample **120**, refers to one or more images or video of one or more fish in enclosure **106** captured by camera **102** and processed by system **100** to estimate a fish mass measurement, a fish count, or a direct fish biomass estimate of the one or more fish.

[0036] Sample **120** may not be representative of the entire fish population in enclosure **106**. In other words, sample **120** can have a bias. The bias can be severe. Severe bias can cause substantial overestimation or underestimation when sample **120** is used by system **100** to estimate a fish mass measurement, a fish count, or a direct fish biomass estimate of all fish in enclosure **106**. Various situational and environment conditions in enclosure **104** can contribute to the bias of sample **120** ("sampling bias"). Such conditions can include the position of camera **102** when sample **120** is captured and the location and spatial distribution of fish within the enclosure **104** when sample **120** is captured.

[0037] To attempt to reduce bias, sample **120** can be captured when the fish in enclosure **106** are being fed. This tends to reduce the spatial distribution of the fish population in enclosure **106** as the fish tend to congregate around where the feed is being dispensed into enclosure **106** by a mechanical feed dispenser above, below, or at water surface **104**. Even so, sample **120** captured at feeding time can still have significant bias. For example, sample **120** can include mostly larger more powerful fish that are able to push out the smaller weaker fish from the area in the enclosure **106** where the feed is being dispensed, or sample **120** can omit fish that are satiated or sick or otherwise not feeding at the time.

[0038] For fish mass measurement, statistical analysis **112** can use a polynomial, linear, power curve, or other mathematical model for computing a fish weight (mass) of a target fish based on one or more fish size parameters for the target fish. Image processing **110** can identify the target fish in sample **120**. For example, image processing **110** can use machine learning-aided image segmentation to identify portions of images or video frames that contain an image of a fish. In some implementations, image processing **110** incorporates a deep convolutional neural network to aid in segmentation of target fish from sample **120**. Image processing **120** can then use two-dimensional (2D) or three-dimensional (3D) image processing techniques to determine from sample **120** the one or more fish size parameters of the target fish for input to the model. A fish size parameter can include an estimated length, area, width, or perimeter of the target fish. The model can be target fish species-specific and can incorporate a bend model to account for a bend of the target fish in sample **120** in case the body of the target fish is not straight in sample **120**. Multiple fish mass measurements of multiple target fish identified in sample **120** can be determined.

[0039] Various computer vision techniques can be employed by image processing **110** to obtain a fish count of sample **120**. Such computer vision techniques can include one or more of the following methods: neural network, data fitting, area counting, curve evolution, fish localization, image thinning, connected component, or object tracking.

[0040] For direct fish biomass estimation, statistical analysis **112** can compute a weight (mass) of a target fish directly by its volume and its density (mass = volume X density). The density of the target fish can be predetermined

such as by the particular species of the target fish. The volume of the target fish can be determined by image processing **110** from sample **120** using various techniques including computer vision technology such as 2D or 3D image processing techniques aided by deep learning such as a convolutional neural network. The computer vision techniques can be aided by laser scanning technology. For example, a LiDAR suitable for underwater use can be affixed to camera **102** for laser scanning fish in imaging direction **118**. For example, a laser scanner in combination with a monocular camera **102** can be used. The laser scanner projects structural light onto the fish and 2D or 3D cartesian coordinates of the fish's surface can be determined based on sample **120** by image processing **110** to represent the fish's shape.

[0041] An overall fish mass measurement, fish count, or direct fish biomass estimate for sample **120** can be determined by statistical analysis **112** as an average, mean, or probability distribution of individual corresponding determinations.

[0042] As mentioned, sample **120** can be biased. Thus, a simple extrapolation method to compute the overall fish mass measurement, fish count, or direct fish biomass estimate for entire enclosure **106** such as by using a fixed multiple applied to sample **120** can result in substantial overestimation or underestimation. To correct for the bias of sample **120**, the disclosed techniques use a bias estimation system. Generally speaking, the bias estimation system obtains data from multiple sensors located underwater in enclosure **106**. The sensors are positioned to sample different volumes of water within enclosure **106** including the volume from which sample **120** was captured. The sensor data provides an estimate of the density of fish in each water volume at a time corresponding to when sample **120** was captured by camera **102**. The extrapolation system computes an overall bias-adjusted fish mass measurement, fish count, or direct fish biomass estimate for entire enclosure **106** based on the fish mass measurement, fish count, or direct fish biomass estimate for sample **120** and the densities determined from the active acoustics sensor data.

[0043] FIG. **2** depicts the computer vision-based aquatic biomass estimation system of FIG. **1** with the addition of a bias estimation system. Bias estimation system encompasses bias estimation sensors **226**, bias estimation functionality **222**, and extrapolation functionality **224**. Bias estimation sensors **226** is sometimes referred to herein as bias estimation sensor array **226**.

[0044] In an implementation, bias estimation sensors **226** are active acoustics sensors. The active acoustics sensors emit sound waves in different directions within enclosure **106** at a certain frequency or set of frequencies to remotely detect fish in enclosure **106**. An active acoustic sensor can be an echosounder or other fish finding transducer, for example.

[0045] An echosounder can have a transducer that emits acoustic waves that propagate within a volume of water within enclosure **106**. When the acoustic waves encounter fish in enclosure **106**, the acoustic waves are reflected back toward the echosounder as an echo signal. Scattered echo signals received back at the transducer of the echosounder are converted into voltage parameters recorded for subsequent analysis. Several fish can be estimated based on the physical characteristic that the strength of the echo signal is

5

proportional to the number of fish (fish density) in the water volume targeted by the echosounder (target water volume).

[0046] Split-beam technology can be used to measure the target strength of fish. An echosounder can project a beam of sound within enclosure **106**. The center of the beam of sound can have more concentrated power. As such, a fish within or near the center of the acoustic beam can result in a strong echo signal. However, the same fish nearer to the edge of the acoustic beam can result in a relatively weaker echo signal. To avoid mistakenly interpreting the weaker echo signal returning from a fish near the edge of the acoustic beam as a smaller sized fish than if the same fish were nearer to the center of the acoustic beam, an echosounder can be configured with a transducer that emits multiple (e.g., three or more) acoustic beams instead of just a single acoustic beam. For example, an echosounder can emit four acoustic beams. By emitting multiple acoustic beams, the position of fish within the overall acoustic beam can be determined to compensate for the difference in echo signal intensity when the fish is nearer to the edge of the overall acoustic beam compared to closer to the center of the overall acoustic beam.

[0047] While an echo sounder can employ split-beam technology, it is not required in an implementation. Instead, an echosounder can emit a single acoustic beam such as, for example, an acoustic beam with a relatively wide cone angle.

[0048] When the fish density is low in the target water volume, an echo counting method can be used to measure fish density by dividing the fish number obtained directly from the echosounder by the volume of the target water volume. When the fish density is relatively high in the target water volume when fish are congregating and cannot be easily identified as single fish, an echo integration method can be used to estimate the number of fishes by dividing the integral value of the echo signal intensity of the fish shoal in the target water volume by the target strength of an individual fish. In either case, an estimate of the number of fish in the target water volume is obtained. More generally, an estimate of the fish density of the target water volume is obtained.

[0049] At least two and up to eight active acoustics sensors can be positioned underwater within enclosure **106**. In the example of FIG. **2**, bias estimation sensors **226** are affixed to the housing of camera **102** and are configured to emit acoustic waves in a plane parallel to imaging direction **118**. For example, two, four, six, or eight bias estimation sensors **226** can be affixed to housing of camera **102**, each positioned in different directions so as to cover different target water volumes within enclosure **106**.

[0050] However, it is also possible for bias estimation sensors **226** to be positioned in a fixed position such as affixed to the cage of enclosure **106**. For example, an active acoustics sensor can be positioned at the bottom of enclosure **106** and configured to emit acoustic waves toward water surface **104** or an active acoustics sensor can be positioned at the top of enclosure **106** configured to emit acoustic waves toward the bottom of enclosure **106**. It is also possible for active acoustic sensors **226** be positioned along the perimeter of enclosure **106** and configured to emit acoustic waves toward the center of enclosure **106**.

[0051] In any case, each bias estimation sensor **226** provides data and information by which bias estimation **222** can determine a fish density for a corresponding target bias esti-

mation sensor water volume (target water volume) within enclosure **106**. The fish density can be based on sensor data and information that is obtained from or determined by bias estimation sensors **226** at a time corresponding to when camera **102** captures sample **120**. In this way, bias estimation sensors **226** provide a general estimate of the fish density in enclosure **106** at a time corresponding to when camera **102** captures sample **120**. Bias estimation **222** can break this total estimate down by target water volume for each bias estimation sensor **226** to obtain a general model of the distribution of the fish density within enclosure **106**. A fish density determined by bias estimation **222** based on data and information obtained from bias estimation sensors **226** can be a fish measurement, a fish count, or a direct fish biomass estimate.

[0052] The size and shape of the target water volume for each bias estimation sensor **226** can be based on a model of the water volume that the sensor is configured to scan which can depend on various such factors including environmental factors such as turbidity of the water within enclosure **106**. The location of the target water volume within enclosure **106** can be based on the location of the corresponding bias estimation sensor **226** and its beam direction. If the sensor is affixed to the housing of camera **102**, then the position of camera **102** when sample **120** is captured can be used to determine the location of the target water volume within enclosure **106** for the sensor. In any case, when camera **102** captures sample **120**, bias estimation sensors **226** can provide data and information for a corresponding set of target water volumes within enclosure **106** from which a fish density can be estimated by bias estimation **222** for each target water volume. Bias estimation **222** can then determine the target water volume or volumes from which sample **120** was captured by camera **102** based on the position of camera **102** at the time sample **120** was captured and the positions of the target water volumes for the sensors **226** at the time sample **120** was captured.

[0053] Bias estimation **222** and extrapolation **224** can then compute a bias adjusted fish mass measurement, fish count, or direct fish biomass estimate for the entire enclosure **106**. The bias adjusted fish mass measurement, fish count, or direct fish biomass estimate can be computed based on the fish mass measurement, fish count, or direct fish biomass estimate computed for sample **120** and the per-target water volume fish densities.

[0054] Generally speaking, a bias adjustment can be computed that reflects how representative the target water volume from which sample **120** was captured (the sample target water volume) is compared to the other target water volumes for the other active acoustics sensors **226**. For example, the fish density for each target water volume can be compared to the total (sum) of all fish densities for all target water volumes for all bias estimation sensors **226** to obtain an estimate of the percentage of the total fish density in enclosure **106** at the time sample **120** was captured. These percentages can be then used to extrapolate the fish mass measurement, the fish count, or the direct fish biomass estimate for the entire enclosure **106** from the fish mass measurement, fish count, or direct fish biomass estimate computed for sample **120**. For example, the extrapolated or bias adjusted fish mass measurement, the fish count, or the direct fish biomass estimate for the entire enclosure **106** can be computed as: $Xe = \sum_{i=1}^{n \geq 2} Pi * Xs$

[0055] Here, Xe represents the extrapolated or bias adjusted fish mass measurement, the fish count, or the direct fish biomass estimate for the entire enclosure **106**. The parameter n represents the number of bias estimation sensors **226** and hence the number of target water volumes. For example, n can range between two and eight or more. The parameter Pi represents the percentage of the total fish density across all target water volumes that is allocated to target water volume i. The parameter Xs represents the fish mass measurement, fish count, or direct fish biomass estimate computed for sample **120**.

[0056] FIG. **3** depicts use of an active acoustic sensor **328** for bias adjustment. In this example, active acoustic sensor **328** is affixed to the housing of camera **102**. Sensor **208** is positioned on the housing of camera **102** to emit the center of its acoustic beam in the same general direction as imaging direction **118**. The housing of camera **102** can be configured with additional active acoustic sensors but positioned to emit the center of their respective acoustic beams in different directions so as to provide greater directional coverage of enclosure **106**. For example, camera **102** can be affixed with four active acoustic sensors with one positioned in the same direction as imaging direction **118**, another positioned in the opposite direction as imaging direction **118**, yet another positioned in a direction perpendicular to imaging direction **118**, and finally another positioned in a direction opposite to the fore mentioned sensor positioning perpendicularly to imaging direction **118**. As an alternative, camera **102** can include four additional active acoustic sensors each positioned to emit the center of its acoustic beam at approximately forty-five degrees between a different pair of active acoustic sensors in the prior example. The number of active acoustic sensors used in an implementation can vary depending on a variety of factors including cost and the maximum effective cone angle of each acoustic beam emitted from the sensors.

[0057] The maximum effective cone angle (swathe angle) of each acoustic beam emitted from the sensors can vary depending on whether the sensors are single-beam or use split-beam technology. For example, a single-beam active acoustic sensor can have an acoustic beam with a cone angle between two (2) and fifteen (15) degrees while a multi-beam or split-beam active acoustic sensor can have an overall acoustic beam with a cone angle (swathe angle) between one hundred and twenty (12) and one hundred and seventy (170) degrees.

[0058] It should be noted that when active acoustic sensor **328** is a multi-beam or split-beam sensor, sensor **328** can emit multiple beams at different frequencies, with different cone angles (different swath angles), and in different directions. In this case, unless the context clearly indicates otherwise, reference above and elsewhere herein to the center of the acoustic beam of sensor **328** encompasses to the center of the centermost acoustic beam emitted by sensor **320**.

[0059] While in the example of FIG. **3**, active acoustic sensor **328** is positioned to emit the center of its acoustic beam substantially parallel to a plane of imaging direction **118**, sensor **328** can be positioned in the housing of camera **102** to emit the center of its acoustic beam at a positive or negative angle upward or downward from a plane of imaging direction **118**. For example, sensor **328** (and the other active acoustic sensors affixed to the housing of camera **102**) can be positioned to emit the center of its acoustic beam at an upward or downward angle between zero (0) and fifteen

(15) degrees above or below a plane of imaging direction **118**.

[0060] Camera **102** has a target imaging water volume **332** within which camera **102** can capture usable quality images or video of fish that freely swim within enclosure **106**. Images or video of fish outside target imaging water volume **332** captured by camera **102** can be unusable by image processing **110** for determining a fish measurement, a fish count, or a direct fish biomass estimate of sample **120**. For example, unable images or video frames can include out-of-focus fish or fish at too low a resolution that result because the fish is outside target imaging water volume **332** when imaged by camera **102**.

[0061] The size and shape of target imaging water volume **332** can vary depending on a variety of characteristics of camera **102** and the application at hand including the desired working distance and depth of focus of camera **102** configuration. Further, size and shape of target imaging water volume **332** can change at times depending on the environmental conditions within enclosure **106** such as the water turbidity and ambient lighting.

[0062] Target water volume **330** represents the volume of water that can be effectively scanned by sensor **328**. Typically, the size of target water volume **330** is greater than the size of target imaging water volume **332**. While in FIG. **3** target imaging water volume **332** is depicted entirely within target water volume **330**, this need not be the case and the volumes can only partially overlap in an implementation.

[0063] In an implementation, instead of bias estimation sensors **226** being active acoustic sensors such as echosounders, bias estimation sensors **226** are active electric field sensors. In such an implementation, a plurality of active electric field electrodes can be placed in enclosure **106** to set an active alternating polarity electric field within enclosure **106**. The frequency of the alternating polarity can sweep over a range of frequencies. An object or objects, conductive or non-conductive, within a target water volume within the electric field can change the capacitance behavior in the target water volume in accordance with the size and the composition of the object(s). Sensor electrodes can be placed in the electric fields to detect the local capacitance signals. From the local capacitance signals, the amount of fish biomass within the target water volume can be determined by bias estimation **222**. A bias estimation sensor **226** can also be the camera itself. In this scenario, computer vision techniques are applied by bias estimation **222** to video captured by the camera as the camera moves about underwater to determine amounts of fish biomass within various target water volumes.

[0064] In some embodiments, in addition to or instead of determine a bias-adjusted biomass estimate, a variance estimate is determined. Additionally, or alternatively, a bias-adjusted biomass estimate, or a variance estimate can be determined based on applying deep learning-based computer vision techniques to video captured by the camera immersed underwater in the net pen. Such techniques can be used to determine the orientation of fish in the video images and swimming direction and this information used to determine a bias-adjusted biomass estimate or variance estimate.

[0065] In some embodiments, a system that implements a portion or all of the techniques described herein can include a general-purpose computer system, such as the computer system **400** illustrated in FIG. **4**, that includes, or is config-

ured to access, one or more computer-accessible media. In the illustrated embodiment, the computer system **400** includes one or more processors **410** coupled to a system memory **420** via an input/output (I/O) interface **430**. The computer system **400** further includes a network interface **440** coupled to the I/O interface **430**. While FIG. 4 shows the computer system **400** as a single computing device, in various embodiments the computer system **400** can include one computing device or any number of computing devices configured to work together as a single computer system **400**.

[0066] In various embodiments, the computer system **400** can be a uniprocessor system including one processor **410**, or a multiprocessor system including several processors **410** (e.g., two, four, eight, or another suitable number). The processor(s) **410** can be any suitable processor(s) capable of executing instructions. For example, in various embodiments, the processor(s) **410** can be general-purpose or embedded processors implementing any of a variety of instruction set architectures (ISAs), such as the x86, ARM, PowerPC, SPARC, or MIPS ISAs, or any other suitable ISA. In multiprocessor systems, each of the processors **410** can commonly, but not necessarily, implement the same ISA.

[0067] The system memory **420** can store instructions and data accessible by the processor(s) **410**. In various embodiments, the system memory **420** can be implemented using any suitable memory technology, such as random-access memory (RAM), static RAM (SRAM), synchronous dynamic RAM (SDRAM), nonvolatile/Flash-type memory, or any other type of memory. In the illustrated embodiment, program instructions and data implementing one or more desired functions, such as those methods, techniques, and data described above, are shown stored within the system memory **420** as biomass estimation code **425** (e.g., executable to implement, in whole or in part, to implement the biomass estimation techniques disclosed herein) and data **426**.

[0068] In some embodiments, the I/O interface **430** can be configured to coordinate I/O traffic between the processor **410**, the system memory **420**, and any peripheral devices in the device, including the network interface **440** and/or other peripheral interfaces (not shown). In some embodiments, the I/O interface **430** can perform any necessary protocol, timing, or other data transformations to convert data signals from one component (e.g., the system memory **420**) into a format suitable for use by another component (e.g., the processor **410**). In some embodiments, the I/O interface **430** can include support for devices attached through various types of peripheral buses, such as a variant of the Peripheral Component Interconnect (PCI) bus standard or the Universal Serial Bus (USB) standard, for example. In some embodiments, the function of the I/O interface **430** can be split into two or more separate components, such as a north bridge and a south bridge, for example. Also, in some embodiments, some or all of the functionality of the I/O interface **430**, such as an interface to the system memory **420**, can be incorporated directly into the processor **410**.

[0069] The network interface **440** can be configured to allow data to be exchanged between the computer system **400** and other devices **460** attached to a network or networks **450**, such as other computer systems or devices as illustrated other figures, for example. In various embodiments, the network interface **440** can support communication via any suitable wired or wireless general data networks, such as types

of Ethernet network, for example. Additionally, the network interface **440** can support communication via telecommunications/telephony networks, such as analog voice networks or digital fiber communications networks, via storage area networks (SANs), such as Fibre Channel SANs, and/or via any other suitable type of network and/or protocol.

[0070] In some embodiments, the computer system **400** includes one or more offload cards **470A** or **470B** (including one or more processors **475**, and possibly including the one or more network interfaces **440**) that are connected using the I/O interface **430** (e.g., a bus implementing a version of the Peripheral Component Interconnect - Express (PCI-E) standard, or another interconnect such as a QuickPath interconnect (QPI) or UltraPath interconnect (UPI)). For example, in some embodiments the computer system **400** can act as a host electronic device (e.g., operating as part of a hardware virtualization service) that hosts compute resources such as compute instances, and the one or more offload cards **470A** or **470B** execute a virtualization manager that can manage compute instances that execute on the host electronic device. As an example, in some embodiments the offload card(s) **470A** or **470B** can perform compute instance management operations, such as pausing and/or un-pausing compute instances, launching and/or terminating compute instances, performing memory transfer/copying operations, etc. These management operations can, in some embodiments, be performed by the offload card(s) **470A** or **470B** in coordination with a hypervisor (e.g., upon a request from a hypervisor) that is executed by the other processors 410A-310N of the computer system **400**. However, in some embodiments the virtualization manager implemented by the offload card(s) **470A** or **470B** can accommodate requests from other entities (e.g., from compute instances themselves), and cannot coordinate with (or service) any separate hypervisor.

[0071] In some embodiments, the system memory **420** can be one embodiment of a computer-accessible medium configured to store program instructions and data as described above. However, in other embodiments, program instructions and/or data can be received, sent, or stored upon different types of computer-accessible media. Generally speaking, a computer-accessible medium can include any non-transitory storage media or memory media such as magnetic or optical media, e.g., disk or DVD/CD coupled to the computer system **400** via the I/O interface **430**. A non-transitory computer-accessible storage medium can also include any volatile or non-volatile media such as RAM (e.g., SDRAM, double data rate (DDR) SDRAM, SRAM, etc.), read only memory (ROM), etc., that can be included in some embodiments of the computer system **400** as the system memory **420** or another type of memory. Further, a computer-accessible medium can include transmission media or signals such as electrical, electromagnetic, or digital signals, conveyed via a communication medium such as a network and/or a wireless link, such as can be implemented via the network interface **440**.

[0072] Various embodiments discussed or suggested herein can be implemented in a wide variety of operating environments, which in some cases can include one or more user computers, computing devices, or processing devices which can be used to operate any of a number of applications. User or client devices can include any of a number of general-purpose personal computers, such as desktop or laptop computers running a standard operating system, as well as cellular, wireless, and handheld devices

8

running mobile software and capable of supporting a number of networking and messaging protocols. Such a system also can include a number of workstations running any of a variety of commercially available operating systems and other known applications for purposes such as development and database management. These devices also can include other electronic devices, such as dummy terminals, thin-clients, gaming systems, and/or other devices capable of communicating via a network.

[0073] Most embodiments use at least one network that would be familiar to those skilled in the art for supporting communications using any of a variety of widely-available protocols, such as Transmission Control Protocol / Internet Protocol (TCP/IP), File Transfer Protocol (FTP), Universal Plug and Play (UPnP), Network File System (NFS), Common Internet File System (CIFS), Extensible Messaging and Presence Protocol (XMPP), AppleTalk, etc. The network(s) can include, for example, a local area network (LAN), a wide-area network (WAN), a virtual private network (VPN), the Internet, an intranet, an extranet, a public switched telephone network (PSTN), an infrared network, a wireless network, and any combination thereof.

[0074] In embodiments using a web server, the web server can run any of a variety of server or mid-tier applications, including HTTP servers, File Transfer Protocol (FTP) servers, Common Gateway Interface (CGI) servers, data servers, Java servers, business application servers, etc. The server(s) also can be capable of executing programs or scripts in response requests from user devices, such as by executing one or more Web applications that can be implemented as one or more scripts or programs written in any programming language, such as Java®, C, C# or C++, or any scripting language, such as Perl, Python, PHP, or TCL, as well as combinations thereof. The server(s) can also include database servers, including without limitation those commercially available from Oracle(®), Microsoft®, Sybase®, IBM®, etc. The database servers can be relational or non-relational (e.g., "NoSQL"), distributed or non-distributed, etc.

[0075] Environments disclosed herein can include a variety of data stores and other memory and storage media as discussed above. These can reside in a variety of locations, such as on a storage medium local to (and/or resident in) one or more of the computers or remote from any or all of the computers across the network. In a particular set of embodiments, the information can reside in a storage-area network (SAN) familiar to those skilled in the art. Similarly, any necessary files for performing the functions attributed to the computers, servers, or other network devices can be stored locally and/or remotely, as appropriate. Where a system includes computerized devices, each such device can include hardware elements that can be electrically coupled via a bus, the elements including, for example, at least one central processing unit (CPU), at least one input device (e.g., a mouse, keyboard, controller, touch screen, or keypad), and/or at least one output device (e.g., a display device, printer, or speaker). Such a system can also include one or more storage devices, such as disk drives, optical storage devices, and solid-state storage devices such as random-access memory (RAM) or read-only memory (ROM), as well as removable media devices, memory cards, flash cards, etc.

[0076] Such devices also can include a computer-readable storage media reader, a communications device (e.g., a modem, a network card (wireless or wired), an infrared communication device, etc.), and working memory as described above. The computer-readable storage media reader can be connected with, or configured to receive, a computer-readable storage medium, representing remote, local, fixed, and/or removable storage devices as well as storage media for temporarily and/or more permanently containing, storing, transmitting, and retrieving computer-readable information. The system and various devices also typically will include a number of software applications, modules, services, or other elements located within at least one working memory device, including an operating system and application programs, such as a client application or web browser. It should be appreciated that alternate embodiments can have numerous variations from that described above. For example, customized hardware might also be used and/or particular elements might be implemented in hardware, software (including portable software, such as applets), or both. Further, connection to other computing devices such as network input/output devices can be employed.

[0077] Storage media and computer readable media for containing code, or portions of code, can include any appropriate media known or used in the art, including storage media and communication media, such as but not limited to volatile and non-volatile, removable and non-removable media implemented in any method or technology for storage and/or transmission of information such as computer readable instructions, data structures, program modules, or other data, including RAM, ROM, Electrically Erasable Programmable Read-Only Memory (EEPROM), flash memory or other memory technology, Compact Disc-Read Only Memory (CD-ROM), Digital Versatile Disk (DVD) or other optical storage, magnetic cassettes, magnetic tape, magnetic disk storage or other magnetic storage devices, or any other medium which can be used to store the desired information and which can be accessed by a system device. Based on the disclosure and teachings provided herein, a person of ordinary skill in the art will appreciate other ways and/or methods to implement the various embodiments.

[0078] In the preceding description, various embodiments are described. For purposes of explanation, specific configurations and details are set forth to provide a thorough understanding of the embodiments. However, it will also be apparent to one skilled in the art that the embodiments can be practiced without the specific details. Furthermore, well-known features can be omitted or simplified in order not to obscure the embodiment being described.

[0079] Bracketed text and blocks with dashed borders (e.g., large dashes, small dashes, dot-dash, and dots) are used herein to illustrate optional operations that add additional features to some embodiments. However, such notation should not be taken to mean that these are the only options or optional operations, or that blocks with solid borders are not optional in certain embodiments.

[0080] Unless the context clearly indicates otherwise, the term "or" is used in the foregoing specification and in the appended claims in its inclusive sense (and not in its exclusive sense) so that when used, for example, to connect a list of elements, the term "or" means one, some, or all of the elements in the list.

[0081] Unless the context clearly indicates otherwise, the terms "comprising," "including," "having," "based on," "encompassing," and the like, are used in the foregoing spe-

cification and in the appended claims in an open-ended fashion, and do not exclude additional elements, features, acts, or operations.

[0082] Unless the context clearly indicates otherwise, conjunctive language such as the phrase "at least one of X, Y, and Z," is to be understood to convey that an item, term, etc. can be either X, Y, or Z, or a combination thereof. Thus, such conjunctive language is not intended to require by default implication that at least one of X, at least one of Y, and at least one of Z to each be present.

[0083] Unless the context clearly indicates otherwise, as used in the foregoing detailed description and in the appended claims, the singular forms "a," "an," and "the" are intended to include the plural forms as well.

[0084] Unless the context clearly indicates otherwise, in the foregoing detailed description and in the appended claims, although the terms first, second, etc. are, in some instances, used herein to describe various elements, these elements should not be limited by these terms. These terms are only used to distinguish one element from another. For example, a first computing device could be termed a second computing device, and, similarly, a second computing device could be termed a first computing device. The first computing device and the second computing device are both computing devices, but they are not the same computing device.

[0085] In the foregoing specification, the techniques have been described with reference to numerous specific details that can vary from implementation to implementation. The specification and drawings are, accordingly, to be regarded in an illustrative rather than a restrictive sense.

What is claimed is:

1. A method for multi-modal aquatic biomass estimation, comprising:

determining a fish mass measurement, a fish count, or a direct fish biomass estimate from a sample of one or more digital images or digital video captured by a digital camera immersed underwater in a fish farm enclosure;

determining a fish density for a water volume within the fish farm enclosure based on an analysis of signals received from a bias estimation sensor immersed underwater in the fish farm enclosure; and

computing a bias-adjusted fish mass measurement, fish count, or direct fish biomass estimate for the fish farm enclosure based on:

(i) the fish mass measurement, the fish count, or the direct fish biomass estimate determined from the sample of one or more digital images or digital video captured by the digital camera immersed underwater in the fish farm enclosure, and

(ii) the fish density determined for the water volume;

wherein the method is performed by one or more computing devices.

2. The method of claim 1, wherein the fish density for the water volume within the fish farm enclosure comprises a fish count for the water volume.

3. The method of claim 1, wherein the bias estimation sensor comprises an active acoustic sensor, and wherein the method further comprises:

determining the fish density for the water volume within the fish farm enclosure based on analysis of echo signals received from the active acoustic sensor.

4. The method of claim 1, wherein the bias estimation sensor comprises an active electric field sensor, and wherein the method further comprises:

determining the fish density for the water volume within the fish farm enclosure based on analysis of capacitance signals received from the active electric field sensor.

5. The method of claim 1, further comprising:

determining a particular water volume of a plurality of water volumes from which at least a portion of the sample of one or more digital images or digital video is captured by the digital camera immersed underwater in the fish farm enclosure;

determining a particular fish density of a plurality of fish densities determined for the particular water volume; and

computing the bias-adjusted fish mass measurement, fish count, or direct fish biomass estimate for the fish farm enclosure based on a percentage of the particular fish density of the plurality of fish densities.

6. The method of claim 1, wherein the bias estimation sensor is affixed to the camera, and wherein the method further comprises determining a particular water volume of the plurality of water volumes from which at least the portion of the sample of one or more digital images or digital video is captured by the digital camera immersed underwater in the fish farm enclosure based on a position of the camera in the fish farm enclosure at a time the sample of one or more digital images or digital video is captured by the digital camera.

7. The method of claim 1, wherein the bias estimation sensor is the digital video camera, the signals received from the bias estimation sensor comprise digital video, and the analysis of the signals comprises applying deep learning computer vision techniques to the digital video to determine the fish density.

8. A method for multi-modal aquatic biomass estimation, comprising:

determining a fish mass measurement, a fish count, or a direct fish biomass estimate from a sample of one or more digital images or digital video captured by a digital camera immersed underwater in a fish farm enclosure;

determining a position of the digital camera in the fish farm enclosure at a time the sample of the one or more digital images or digital video is captured by the digital camera; and

computing a bias-adjusted fish mass measurement, fish count, or direct fish biomass estimate for the fish farm enclosure based on:

(i) the fish mass measurement, the fish count, or the direct fish biomass estimate determined from the sample of the one or more digital images or digital video captured by the digital camera immersed underwater in the fish farm enclosure, and

(ii) the position of the digital camera in the fish farm enclosure at the time the sample of the one or more digital images or digital video is captured by the digital camera.

9. The method of claim 8, further comprising:

determining a fish density for a water volume within the fish farm enclosure based on an analysis of signals received from a bias estimation sensor immersed underwater in the fish farm enclosure; and

computing the bias-adjusted fish mass measurement, fish count, or direct fish biomass estimate for the fish farm enclosure based on:

the fish density for the water volume.

10. The method of claim **9**, wherein the fish density for the water volume within the fish farm enclosure comprises a fish count for the water volume.

11. The method of claim **9**, wherein the bias estimation sensor comprises an active acoustic sensor, and wherein the instructions, when executed by one or more computing devices, cause the one or more computing devices to perform:

determining the fish density for the water volume within the fish farm enclosure based on analysis of echo signals received from the active acoustic sensor.

12. The method of claim **9**, wherein the bias estimation sensor comprises an active electric field sensor, and wherein the instructions, when executed by one or more computing devices, cause the one or more computing devices to perform:

determining the fish density for the water volume within the fish farm enclosure based on analysis of capacitance signals received from the active electric field sensor.

13. The method of claim **9**, wherein the bias estimation sensor is the digital video camera, the signals received from the bias estimation sensor comprise digital video, and the analysis of the signals comprises applying deep learning computer vision techniques to the digital video to determine the fish density.

14. A method for multi-modal aquatic biomass estimation, comprising:

determining a fish mass measurement, a fish count, or a direct fish biomass estimate from a sample of one or more digital images or digital video captured by a digital camera immersed underwater in a fish farm enclosure;

determining a fish density for a water volume within the fish farm enclosure based on an analysis of signals received from a bias estimation sensor immersed underwater in the fish farm enclosure;

determining a position of the digital camera in the fish farm enclosure at a time the sample of the one or more digital images or digital video is captured by the digital camera; and

computing a bias-adjusted fish mass measurement, fish count, or direct fish biomass estimate for the fish farm enclosure based on:

(i) the fish mass measurement, the fish count, or the direct fish biomass estimate determined from the sample of the one or more digital images or digital video captured by the digital camera immersed underwater in the fish farm enclosure,

(ii) the fish density for the water volume, and

(iii) the position of the digital camera in the fish farm enclosure at the time the sample of the one or more

digital images or digital video is captured by the digital camera.

15. The method of claim **14**, wherein the fish density for the water volume within the fish farm enclosure comprises a fish count for the water volume.

16. The method of claim **14**, wherein the bias estimation sensor comprises an active acoustic sensor, and wherein the method further comprises:

determining the fish density for the water volume within the fish farm enclosure based on analysis of echo signals received from the active acoustic sensor.

17. The method of claim **14**, wherein the bias estimation sensor comprises an active electric field sensor, and wherein the method further comprises:

determining the fish density for the water volume within the fish farm enclosure based on analysis of capacitance signals received from the active electric field sensor.

18. The method of claim **14**, further comprising:

determining a particular water volume of a plurality of water volumes from which at least a portion of the sample of one or more digital images or digital video is captured by the digital camera immersed underwater in the fish farm enclosure;

determining a particular fish density of a plurality of fish densities determined for the particular water volume; and

computing the bias-adjusted fish mass measurement, fish count, or direct fish biomass estimate for the fish farm enclosure based on a percentage of the particular fish density of the plurality of fish densities.

19. The method of claim **14**, wherein the bias estimation sensor is affixed to the camera, and wherein the method further comprises determining a particular water volume of the plurality of water volumes from which at least the portion of the sample of one or more digital images or digital video is captured by the digital camera immersed underwater in the fish farm enclosure based on a position of the camera in the fish farm enclosure at a time the sample of one or more digital images or digital video is captured by the digital camera.

20. The method of claim **14**, wherein the bias estimation sensor is the digital video camera, the signals received from the bias estimation sensor comprise digital video, and the analysis of the signals comprises applying deep learning computer vision techniques to the digital video to determine the fish density.

* * * * *
