(54) Title: COMBINING NARROWBAND APPLICATIONS WITH BROADBAND TRANSPORT

(57) Abstract: The combination of narrowband applications with broadband transport is enabled by combining a first node having narrowband ability with a second node having broadband ability in which the first node has at least call control functionality, and the second node has connection control functionality and associated switching capabilities. The second node may rely on the call control functionality of the first node for traffic handling functions. Communications between the two nodes may be effectuated over first and second links for call signaling information and call data information, respectively. When switching fabric for call data information is present in both of the first and second nodes, incoming calls to either node may be routed as an outgoing call from the other node in order to, for example, switch between broadband and narrowband transport mechanisms.

**COMBINING NARROWBAND APPLICATIONS WITH BROADBAND TRANSPORT****CROSS-REFERENCES TO RELATED APPLICATIONS**

5           This Nonprovisional Application for Patent is a Continuation-in-Part of U.S. Nonprovisional Application for Patent Serial No. 09/353,135, filed on July 14, 1999. U.S. Nonprovisional Application for Patent Serial No. 09/353,135 is hereby incorporated by reference in its entirety herein.

10           This Nonprovisional Application for Patent is related by subject matter to U.S. Nonprovisional Applications for Patent Nos. 09/764,622 (Attorney Docket No. 27493-00397USPT), 09/764,960 (Attorney Docket No. 27493-00409USPT), and 09/764,953 (Attorney Docket No. 27493-15 00410USPT), all of which are filed on even date herewith. These U.S. Nonprovisional Applications for Patent Nos. 09/764,622, 09/764,960, and 09/764,953 are hereby incorporated by reference in their entirety herein.

**20 BACKGROUND OF THE INVENTION****Technical Field of the Invention**

The present invention relates in general to the field of communications, and in particular, by way of example but not limitation, to using broadband transport for narrowband  
25 telephony and data communications.

**Description of Related Art**

The increasing interest for high band services such as multimedia applications, video on demand, video telephone,  
30 and teleconferencing has motivated development of the Broadband Integrated Service Digital Network (B-ISDN). B-ISDN is based on a technology known as Asynchronous

-2-

Transfer Mode (ATM) and offers considerable extension of telecommunications capabilities.

ATM is a packet-oriented transfer mode which uses asynchronous time division multiplexing techniques. The packets are called cells and traditionally have a fixed size. A traditional ATM cell comprises 53 octets, five of which form a header and 48 of which constitute a "payload" or information portion of the cell. The header of the ATM cell includes two quantities that are used to identify a connection in an ATM network over which the cell is to travel. These two quantities include the Virtual Path Identifier (VPI) and the Virtual Channel Identifier (VCI).

In general, a virtual path is a principal path defined between two switching nodes of the network; a virtual channel is one specific connection on the respective principal path.

At its termination points, an ATM network is connected to terminal equipment, e.g., ATM network users. In between ATM network termination points, there are typically multiple switching nodes. The switching nodes have ports which are connected together by physical transmission paths or links. Thus, in traveling from an originating terminal equipment to a destination terminal equipment, ATM cells forming a message may travel through several switching nodes and the ports thereof.

Of the multiple ports of a given switching node, each may be connected via a link circuit and a link to another node. The link circuit performs packaging of the cells according to the particular protocol in use on the link. A cell that is incoming to a switching node may enter the switching node at a first port and exit from a second port via a link circuit onto a link connected to another node. Each link can carry cells for multiple connections, with

each connection being, e.g., a transmission between a calling subscriber or party and a called subscriber or party.

The switching nodes each typically have several  
5 functional parts, a primary of which is a switch core. The switch core essentially functions like a cross-connect between ports of the switch. Paths internal to the switch core are selectively controlled so that particular ports of the switch are connected together to allow a message to  
10 travel from an ingress side/port of the switch to an egress side/port of the switch. The message can therefore ultimately travel from the originating terminal equipment to the destination terminal equipment.

While ATM, because of the high speed and bandwidth  
15 that it offers, is envisioned as the transport mechanism for more advanced services such as B-ISDN, it nevertheless must be recognized that the current narrowband networks (e.g., Public Switched Telephone Networks (PSTN), ISDN, etc.) will remain in use (at least in part) for quite some  
20 time. It has taken decades for the present voice switched telephony networks (e.g., PSTN, ISDN, etc.) to reach their present advanced functionalities. While ATM networks are being built, the ATM networks will likely not easily acquire all the functionalities of advanced voice  
25 communication. Therefore, at least initially, ATM networks/nodes will in some instances be added to parts or will replace parts of circuit switched telephony networks.

In such instances, ATM will be used for transport and switching. ATM can actually be used as a single transport  
30 and switching mechanism for multiple other networks, including multiple other different types of networks. For example, a single ATM network can be used to transport and switch communications from mobile networks (e.g., Public

Land Mobile Networks (PLMNs)), Internet protocol (IP)-based networks (e.g., the Internet), etc., as well as landline networks such as PSTNs and ISDNs.

United States Patent Nos. 5,568,475 and 5,483,527 to  
5 Doshi et al., for example, incorporate ATM switches for routing telephony voice signals between Synchronous Transfer Mode (STM) nodes. The ATM switches use a signaling system No. 7 (SS#7) network to establish a virtual connection, rather than a circuit switched  
10 connection, as would be the case in pure STM network. The signaling system No. 7 (SS#7) network of United States Patents 5,568,475 and 5,483,527 includes signal transfer points (STPs) that are connected by special physical links to each of the ATM switch nodes. For call setup, for  
15 example, signaling messages are relayed through the non-ATM signaling system No. 7 (SS#7) network. In such relaying, a non-ATM STP receives the signaling message and advises its associated ATM node of the call setup. The associated ATM node may then identify idle resources to be used for  
20 forwarding voice signals to the next ATM node once the call has been setup, and it may prepare its own signaling message to be used in the relay.

The signaling message for the relay that is prepared by the ATM node is returned to its associated STP, which  
25 forwards the signaling message via the signaling system No. 7 (SS#7) network to another STP associated with the next ATM node. Such relaying continues until the signaling message reaches an STP of an STM local exchange carrier (LEC). Once the call has been set up, the ensuing speech  
30 (or voice-band data) is transported via the ATM nodes. STM/ATM terminal adapters are situated between the STM network and the ATM network for packing samples of voice signals as received from the STM network into ATM cells for

application to the ATM network, and for unpacking ATM cell payloads to obtain voice signals for application to the STM network from the ATM network. The incorporation of ATM into an STM network in the particular manner as described above thus involves a non-ATM signaling network alongside the ATM nodes. Furthermore, each STP node associated with an ATM node performs only call control functions in the network of Doshi et al. Otherwise and in general, call control and connection control is traditionally combined in conventional communication nodes.

With reference now to FIG. 1A, a conventional unified communications node is illustrated at 100. The conventional unified communications node 100 may represent any general purpose switching node in a telecommunications network such as a PSTN. Within the conventional communications node 100, the call control 105 functions and the connection control 110 functions are united. The call control 105 and the connection control 110 functions together encompass the entire seven (7) layers of the Open System Interconnection (OSI) protocol. These seven (7) layers are denoted as the physical, data link, network, transport, session, presentation, and application layers.

Accordingly, the conventional communications node 100 may perform all functions related to both switching intelligence and switching fabric. Conventional communication nodes 100 are not, however, capable of handling the interworking between (i) narrowband telephony and data communications and (ii) broadband communications using faster and higher bandwidth networks, such as ATM networks.

With reference now to FIG. 1B, a conventional approach to separating functions of the conventional unified communications node of FIG. 1A is illustrated generally at

150. Conventional approaches attempt to meet the stringent demands of interworking narrowband telephony and data communications with broadband networks using ATM by separating control functions. Specifically, call control  
5 155 functions are separated from connection control 160 functions. The call control 155 functions are thereby made independent of any particular set of connection control 160 functions. This separation is typically accomplished by utilizing a conventional communications node (such as the  
10 conventional communications node 100 of FIG. 1A) that is stripped of its switching intelligence, leaving only the connection control 160. In effect, a conventional communications node 100 is modified by removing or rendering inoperative the call control 105 functions, thus  
15 leaving only the connection control 110 functions. This modified conventional communications node is substituted as the connection control 160 part. The call control 155 part, on the other hand, is typically designed and created without relying on traditional telecommunications hardware  
20 or software.

With reference now to FIG. 2, an existing scheme for utilizing a broadband network in conjunction with nodes corresponding to separated functions of a conventional unified communications node is illustrated generally at  
25 200. Switching intelligence 205A,205B parts are connected to switching fabric 210A,210B parts. The switching fabric 210A,210B parts are connected to the ATM network 215, and they effect required emulation and cell packing for interworking a narrowband network (not shown) with the ATM  
30 network 215. The switching intelligence 205A,205B parts are usually realized with a UNIX-based server. The switching intelligence 205A,205B parts are intended to provide the advanced calling services and features (e.g.,

-7-

those traditionally provided by the Intelligence Network (IN)). The switching intelligence 205A,205B parts do not include any switching fabric resources, so they must rely on the switching fabric 210A,210B parts for these  
5 resources.

Because the switching intelligence 205A,205B parts do not have any of their own switching fabric resources, they are not directly connected to any transport mechanisms, nor do they include the requisite interface(s) for doing so.  
10 Incoming calls are therefore received at a switching fabric 210 part and managed by the associated switching intelligence 205 part. When an incoming call is received at a switching fabric 210 part, call signaling information is sent to the switching intelligence 205 part. The  
15 switching intelligence 205 part performs the appropriate call control functions and sends instructions (e.g., in the form of call signaling information) to the switching fabric 210 part. The switching fabric 210 part follows the instructions by making the appropriate connections (e.g.,  
20 to/through the ATM network 215, to/through a narrowband network (not shown), etc.) for forwarding the call data information for the incoming call. As such, no call data information is (or can be) sent to the switching intelligence 205 part, including from the switching fabric  
25 210 part.

Furthermore, while UNIX-based servers, which realize the switching intelligence 205 parts, may be designed to operate at high speeds, they suffer from a number of deficiencies. First, significant research, design, and  
30 testing is required to produce appropriate software code to run the UNIX-based servers as switching intelligence 205 parts. Existing circuit-switched voice telephony networks include many advanced features that require many lines of

-8-

code that have been gradually developed, tested, and implemented over many years. Duplicating the diverse number and types of features while maintaining the required level of reliability and service using newly written code on a UNIX server is not only a daunting task, but it is also virtually impossible to achieve quickly. Second, it is extraordinarily difficult to migrate gradually from traditional network architectures (e.g., those using the conventional unified communications node 100 of FIG. 1A) to next generation networks that rely on broadband transport mechanisms when deploying nodes with only the switching intelligence 205 part. System operators are essentially forced to simultaneously replace whole portions of their networks in large chunks. The consequential large capital expenditures are naturally undesirable to system operators.

#### **SUMMARY OF THE INVENTION**

The deficiencies of the prior art are overcome by the methods, systems, and arrangements of the present invention. For example, as heretofore unrecognized, it would be beneficial to re-use and/or extend the life of existing switches when combining narrowband networks with broadband transport mechanisms. In fact, it would be beneficial to utilize existing switches to enable a gradual migration from narrowband networks to broadband transport mechanisms via the implementation of hybrid switches.

The present invention is directed to employing first and second nodes in a communications system to combine narrowband and broadband transport mechanisms. The first node includes call control (and optionally connection control) functions while the second node includes connection control functions. The second node may rely on the call control functions of the first node in order to

initiate, complete, and/or forward connections in the communications system. In accordance with certain principles of the present invention, communications between the first and second nodes may involve both data and signaling information. The data and signaling information may optionally be transmitted over separate links. Furthermore, in certain embodiment(s), incoming data and signaling information may be piped from one node to the other without reformatting and/or without needing to indicate whether transmitted/piped information is data-related or signaling-related.

With respect to certain embodiment(s) in accordance with the present invention, a call that is incoming at the first node may be forwarded via a connection of the second node. Likewise, a call that is incoming at the second node may be forwarded via a connection of the first node. Forwarding a call using a node to which the call was not initially incoming may be accomplished by transferring both signaling and data information over one or more links connecting two nodes. For example, when a call is incoming at a second node, signaling information related thereto may be sent to the first node for analysis. If the first node determines that the call can only or can better be handled by forwarding the call from a connection of the first node, then the second node is so instructed, and data information related to the call is sent from the second node to the first node for subsequent forwarding therefrom.

The above-described and other features of the present invention are explained in detail hereinafter with reference to the illustrative examples shown in the accompanying drawings. Those skilled in the art will appreciate that the described embodiments are provided for

purposes of illustration and understanding and that numerous equivalent embodiments are contemplated herein.

#### **BRIEF DESCRIPTION OF THE DRAWINGS**

5           A more complete understanding of the methods, systems, and arrangements of the present invention may be had by reference to the following detailed description when taken in conjunction with the accompanying drawings wherein:

10           FIG. 1A illustrates a conventional unified communications node;

          FIG. 1B illustrates a conventional approach to separating functions of the conventional unified communications node of FIG. 1A;

15           FIG. 2 illustrates an existing scheme for utilizing a broadband network in conjunction with nodes corresponding to separated functions of a conventional unified communications node;

20           FIG. 3 illustrates an exemplary schematic view of a hybrid STM/ATM network according to an embodiment of the invention;

          FIG. 3A illustrates an exemplary schematic view of selected portions of the hybrid STM/ATM network of FIG. 3, and further showing various operational events;

25           FIG. 3B illustrates an exemplary schematic view of a hybrid STM/ATM network according to another embodiment of the invention;

30           FIG. 3C illustrates an exemplary schematic view showing a transit hybrid node pair of the invention connected between two local exchange hybrid node pairs of the invention;

          FIG. 3D illustrates a diagrammatic view of an exemplary protocol between two elements of the network of

the embodiment(s) of the invention that include hybrid node pairs;

FIGS. 3E, 3F, and 3G illustrate diagrammatic views of alternate exemplary protocols between two elements, a first  
5 of the network elements having a hybrid node pair in accordance with embodiment(s) of the invention and a second of the network elements being an access node with an additional ATM interface having circuit emulation;

FIG. 3H illustrates an exemplary diagrammatic view  
10 showing gradual upgrading of a network from a traditional narrowband STM-transported-and-switched environment into an environment with a hybrid STM/ATM network in accordance with embodiment(s) of the invention;

FIG. 3I illustrates an exemplary schematic view  
15 showing a multi-switch hybrid node according to yet another embodiment of the invention;

FIG. 4 illustrates another exemplary scheme for utilizing a broadband network in conjunction with nodes having partially separated functions in accordance with the  
20 present invention;

FIG. 5 illustrates yet another exemplary scheme for utilizing a broadband network in conjunction with nodes having partially separated functions in accordance with the present invention;

FIG. 6 illustrates another exemplary hybrid switch  
25 with multiple ports for switching a connection in accordance with the present invention;

FIG. 7 illustrates a simplified block diagram of an exemplary hybrid switch in accordance with the present  
30 invention;

FIG. 8 illustrates exemplary communications and connections between nodes in another simplified block

-12-

diagram of an exemplary hybrid switch in accordance with the present invention; and

FIG. 9 illustrates an exemplary method in flowchart form for communicating between nodes in a hybrid switch in accordance with the present invention.

#### DETAILED DESCRIPTION OF THE DRAWINGS

In the following description, for purposes of explanation and not limitation, specific details are set forth, such as particular architectures, interfaces, circuits, logic modules (implemented in, for example, software, hardware, firmware, some combination thereof, etc.), techniques, etc. in order to provide a thorough understanding of the invention. However, it will be apparent to one of ordinary skill in the art that the present invention may be practiced in other embodiments that depart from these specific details. In other instances, detailed descriptions of well-known methods, devices, logical code (e.g., hardware, software, firmware, etc.), etc. are omitted so as not to obscure the description of the present invention with unnecessary detail.

A preferred embodiment of the present invention and its advantages are best understood by referring to FIGS. 1A-9 of the drawings, like numerals being used for like and corresponding parts of the various drawings.

In certain embodiments in accordance with the invention (e.g., including embodiment(s) of the invention of the parent application), ATM is used as a transport and switching mechanism in a hybrid STM/ATM network, while the signaling remains normal narrowband signaling. The narrowband signaling may be transported on permanent paths over ATM connections, and the narrowband speech channels

-13-

may be transported on ATM and switched on a "per call basis" (e.g., on-demand) through an ATM switch.

The hybrid STM/ATM network has an access node which services narrowband terminals and which generates a signaling message in connection with call setup. A translator formats the first signaling message into ATM cells so that the first signaling message can be routed through an ATM switch to a circuit switched (e.g., STM) node. The circuit switched node (e.g., PSTN/ISDN) sets up a physical connection for the call and generates a further signaling message for the call, the further signaling message pertaining to the physical connection. The ATM switch routes an ATM-cell-formatted version of the further signaling message to another ATM switch over an ATM physical interface. Thus, the ATM switch switches both narrowband traffic and signaling for the call over the ATM physical interface. The ATM physical interface thus carries an ATM-cell-formatted version of the further signaling message amidst ATM traffic cells.

In view of the fact that the circuit switched node and the ATM switch employ different parameters (e.g., b-channel, etc., for the STM node and VP/VC for the ATM switch), in one embodiment the STM node obtains global position numbers (GPN) for use in setting a path for the further signaling message through the ATM switch. In this regard, at the circuit switched node a translation is made from STM to GPN using an STM/GPN translation table; at the ATM node a translation is made from GPN to VP/VC/port using a GPN/ATM translation table.

The ATM-cell-formatted version of the further signaling message is transported over the ATM physical link and ultimately reaches a destination access node which serves a destination terminal. A destination translator

-14-

unpacks ATM cells carrying the ATM-cell-formatted version of the further signaling message to obtain the STM signaling information for use by the destination access node. The translators may be situated at the access node, 5 for example. In illustrated embodiment(s), the ATM switches are situated at nodes distinct from the PSTN/ISDN nodes, but such need not be the case in other embodiment(s). The signaling messages can be in accordance with the signaling system no. 7 (SS#7) convention, and the 10 further signaling message can be one of an ISUP or a TUP message, for example.

Referring now to FIG. 3, an exemplary hybrid STM/ATM network 320 according to an embodiment of the invention is illustrated. Narrowband terminal devices communicate with 15 hybrid STM/ATM network 320 through access nodes, such as access node 322<sub>o</sub> and access node 322<sub>d</sub>. For example, FIG. 3 shows terminals 324<sub>o</sub> connected to access node 322<sub>o</sub>, particularly ISDN terminal 324<sub>o-I</sub> and PSTN terminal 324<sub>o-P</sub>. Similarly, access node 322<sub>d</sub> has access terminals 324<sub>d</sub> 20 connected thereto, namely ISDN terminal 324<sub>d-I</sub> and PSTN terminal 324<sub>d-P</sub>. Of course, a differing (and most likely greater) number of terminals can be connected to each access node 322, but for simplicity only two such terminals are shown for exemplary purposes in FIG. 3. It should be 25 noted that, as used herein, the term "access node" is not limited to a simple node used merely for connecting subscriber lines, for it may encompass other nodes such as a local exchange (LE) node, for example.

The hybrid STM/ATM network 320 of FIG. 3 comprises one 30 or more STM nodes, also known as PSTN/ISDN nodes 330. While only two such PSTN/ISDN nodes 330<sub>1</sub> and 330<sub>2</sub> are shown in FIG. 3 for sake of illustration, it should be understood that the invention is not limited to only two such nodes.

The structure and operation of conventional PSTN/ISDN nodes 330 are well known; such as those typified by utilization of Ericsson AXE switches, for example. Therefore, only selected pertinent portions of conventional PSTN/ISDN nodes 330 are described herein with reference to PSTN/ISDN node 330<sub>1</sub>. For example, PSTN/ISDN node 330<sub>1</sub> has processor(s) 332 which execute, e.g., node application software including switch and resource control software 333. Such software is used to control STM circuit switch 335 as well as signaling terminals 337 which comprise PSTN/ISDN node 330<sub>1</sub>. Other details of the structure and operation of a conventional PSTN/ISDN node are understood, for example, from United States Patent Application Serial No. 08/601,964 for "Telecommunications Switching Exchange", which is hereby incorporated by reference in its entirety herein.

The STM/ATM network 320 of certain embodiment(s) of the invention is considered a hybrid network in view of the fact that ATM nodes 340 are also included therein. As explained hereinafter, the ATM nodes 340 are used not only to route narrowband traffic between access nodes 322, but also for transport of signaling in ATM cells over an ATM physical interface. In the illustrated example, the ATM network aspect includes two exemplary ATM nodes, particularly ATM node 340<sub>1</sub> and ATM node 340<sub>2</sub>, which are connected by ATM physical interface or link 341. Again, it should be understood that the ATM component can (and typically does) comprise a greater number of ATM nodes, with the nodes being connected by ATM physical links.

In hybrid network 320, a PSTN/ISDN node 330 and a ATM node 340 can be paired together in the manner illustrated in FIG. 3. With such a pair, the PSTN/ISDN node 330 and ATM node 340 are collectively referred to as hybrid node

-16-

pair 330/340. The network 320 of certain embodiment(s) of the invention thus can comprise any number of hybrid node pairs 330/340. An ATM node such as ATM node 340 takes on differing configurations, but commonly has a main processor 5 342 or the like which executes application software including switch and resource control software as generally depicted by 343 in FIG. 3. The heart of an ATM node is usually the ATM switch core or switch fabric, which for the illustrated embodiment is shown as ATM cell switch 345 in 10 FIG. 3. Further information regarding an exemplary ATM switch is provided by United States Patent Application Serial No. 08/188,101, entitled "Asynchronous Transfer Mode Switch", filed November 9, 1998, which is hereby incorporated by reference in its entirety herein. ATM cell 15 switch 345 has plural ingress ports and plural egress ports, with at least some of such ports having a device board attached thereto.

Each device board at ATM node 340 can have one or more different functions performed thereby or one or more 20 different devices mounted thereon. For example, one of the device boards attached to a port of ATM cell switch 345 can, in one embodiment, have the main processor 342 mounted thereon. Other device boards may have other processors, known as "board processors". Some device boards serve as 25 extension terminals (ETs) 346 which may be used to connect the ATM node to other nodes. For example, the ATM physical link 341 shown in FIG. 3 has a first end connected to an extension terminal ET 346<sub>1</sub> of ATM node 340<sub>1</sub>, while a second end of ATM physical link 341 is connected to an 30 unillustrated extension terminal ET of ATM node 340<sub>2</sub>. The device boards connected to ATM cell switch 345 of ATM node 340 are not specifically illustrated in detail in FIG. 3, but the structure and operation of such device boards is

understood with reference to (for example) the following United States Patent Applications, all of which are hereby incorporated by reference in their entirety herein: U.S. Patent Application Serial No. 08/893,507 for "Augmentation  
5 of ATM Cell With Buffering Data"; U.S. Patent Application Serial No. 08/893,677 for "Buffering of Point-to-Point and/or Point-to-Multipoint ATM Cells"; U.S. Patent Application Serial No. 08/893,479 for "VPNC Look-Up Function"; U.S. Patent Application Serial No. 09/188,097  
10 for "Centralized Queuing For ATM Node", filed November 9, 1998.

As explained hereinafter, signaling (e.g., for call setup) is routed from an access node 322 through an ATM node 340 to an appropriate one of the PSTN/ISDN nodes 330.  
15 Such being the case, a circuit emulation or translator 350 is provided for each access node 322 which communicates with an ATM node 340. The translators 350 serve, e.g., to encapsulate signaling information from the access node 322 into ATM cells for signaling directed toward an ATM node  
20 340, and conversely unpack ATM payloads received from an ATM node 340 to extract signaling information for use by the access node 322. In the illustrated embodiment, the translators 350 are preferably provided at or proximate to their associated access nodes 322. That is, translator 350<sub>a</sub>  
25 may be situated at or included in access node 322<sub>a</sub>; translator 350<sub>b</sub> may be situated at or included in access node 322<sub>b</sub>. A pair of physical links, shown as links 351, are provided for connecting each access node 322 to a corresponding one of the ATM nodes 340.

30 ATM node 340 is connected to a PSTN/ISDN node 330 by a physical link 360. With reference to ATM node 340<sub>1</sub>, for example, a pair of switch-to-switch links 360 is employed to connect ATM cell switch 345 (through its circuit

-18-

emulation board 370) to STM circuit switch 335 of PSTN/ISDN node 330, for the carrying of signaling messages. One of the links in pair 360 carries messages from ATM cell switch 345 (after translation at circuit emulation board 370) to  
5 STM circuit switch 335, the other link of the pair 360 carries messages in the reverse direction.

In the illustrated embodiment, a dedicated VPI, VCI internal to ATM cell switch 345 is used for signaling. Thus, with reference to ATM node 340<sub>1</sub>, for example, link  
10 351<sub>0</sub> is connected to extension terminal (ET) 346<sub>2</sub>, which in turn is connected to a first pair of dedicated ports of ATM cell switch 345. Signaling messages received at ATM node 340<sub>1</sub> which are destined to PSTN/ISDN node 330<sub>1</sub> are routed on the dedicated internal VPI/VCI to a port of ATM cell switch  
15 345 which ultimately connects (via circuit emulator 370) to switch-to-switch links 360. However, since the signaling routed through ATM cell switch 345 is encapsulated in ATM cells, a translation to the STM signaling must be performed prior to transmitting the signaling information on switch-  
20 to-switch links 360. For this reason, a device board connected to switch-to-switch links 360 has the circuit emulation (CE) or translator 370 mounted thereon.

The circuit emulation (CE) or translator 370 serves to unpack signaling information which is destined to PSTN/ISDN  
25 node 330, but contained in ATM cells, so that the signaling information can be extracted from the ATM cells prior to application on switch-to-switch links 360. Conversely, signaling information received from PSTN/ISDN node 330<sub>1</sub> on switch-to-switch links 360 at translator 370 is  
30 encapsulated into ATM cells for routing through ATM node 340<sub>1</sub>. From FIG. 3 it can also be seen that a plurality of interfaces 300a-300f are utilized in the hybrid STM/ATM network 320 of certain embodiment(s) of the invention.

These interfaces are described below, primarily with reference to the exemplary nodes (e.g., PSTN/ISDN node 330<sub>1</sub> and ATM node 340<sub>1</sub>).

Interface 300a is a logical interface which exists  
5 between processor(s) 332 of PSTN/ISDN node 330<sub>1</sub> and main processor(s) 342 of ATM node 340<sub>1</sub>. Interface 300a enables PSTN/ISDN node 330 to control the ATM node 340 connected thereto. That is, with the signaling carried by interface 300a, PSTN/ISDN node 330<sub>1</sub> can order physical connections  
10 which are to be set up in ATM node 340<sub>1</sub>. Interface 300a can be a proprietary interface or an open interface (such as a General Switch Management Protocol (GSMP) interface [see Request For Comments (RFC) 1987]). Logical interface 300a can be carried on any physical interface, such as interface  
15 360 described below. Alternatively, interface 300a can be carried by a separate link (e.g., between processors 332 and 342), or carried on top of IP/Ethernet links.

Interface 300b is the signaling between the PSTN/ISDN nodes 330 and the access node 322 connected thereto.  
20 Interface 300b is carried on one or more semipermanent connections through the STM circuit switch 335; through the interworking unit with circuit emulation 370 into ATM cell switch 345; and over permanent virtual connections to access node 322 (particularly to translator 350 in access  
25 node 322, where it is emulated back and terminated). As mentioned above, translator 350 is employed to encapsulate the narrowband signaling from an access node 322 in ATM cells for use by an ATM node 340, and conversely for unpacking ATM cells with signaling information for use by  
30 an access node 322. Each STM channel on the user side may have a corresponding VPI/VCI on interface 300b.

Interface 300c is the non-broadband signaling that is carried through and between the nodes. Interface 300c thus

carries the normal signaling system No. 7 (SS#7) interface (e.g., TUP or ISUP) which is transparently carried in ATM-cell-formatted versions of signaling messages over ATM physical link 341. In PSTN/ISDN node 330, the signaling terminals 337 are used for common channel signaling. In at least one embodiment, signaling terminals 337 can be pooled devices situated at STM circuit switch 335. Alternatively, the signaling terminals 337 can be connected directly to the interfaces between the STM and ATM switches.

10       Interface 300d is the physical interface provided by switch-to-switch link 360. Interface 300d can be used to carry speech for a call to and from an STM network, and also to carry the signaling of interface 300b and interface 300c as described herein. In addition, interface 300d can also be used to link-in special equipment that is to be connected to a normal circuit switch (e.g., conference equipment, answering machines, etc.). Interface 300d can be realized by any standard physical media, such as E1, for example; it being understood that STM-1 or similar speeds 15 may be suitable. The physical interface 300d can also carry the voice data for a conversation between any of the terminals shown in FIG. 3 and an unillustrated terminal connected to the circuit switched network, in which situation the hybrid node pair 330/340 acts as a gateway.

25       Interface 300e is the ATM physical link 341 to other ATM nodes. Any standard link for ATM may be employed for interface 300e. A dedicated VP/VC is employed to transparently transfer the signaling system no. 7 (SS#7) signaling between PSTN/ISDN nodes 330 over interface 300e.

30       Interface 300f, shown in FIG. 3 as connecting each access node 322 with its terminals, is a typical user-network interface (e.g., ISDN, BA/BRA, PRA/PRI, two-wire PSTN, etc.).

-21-

For two traditional circuit switched PSTN/ISDN nodes to communicate with one another using protocols such as ISUP or TUP, it is preferable that ISUP entities in both PSTN/ISDN nodes have coordinated data tables. In this regard, each of the two PSTN/ISDN nodes has a table which translates a CIC value onto a same timeslot in a same physical interface connecting the two PSTN/ISDN nodes. Thus, a CIC value (together with a point code) represents a particular timeslot on a particular physical link. One specific CIC preferably points out the same time slot in the tables of both PSTN/ISDN nodes. In other words, the data tables of the two PSTN/ISDN nodes are preferably coordinated.

The need to coordinate the data tables of PSTN/ISDN node 330<sub>1</sub> and PSTN/ISDN node 330<sub>2</sub> for ISUP/TUP similarly exists in certain embodiment(s) of the invention. If two hybrid nodes 330<sub>1</sub>/340<sub>1</sub> and 330<sub>2</sub>/340<sub>2</sub> have a communication channel set up between them, by means of a semipermanent connection carrying SS#7 signaling for example, the translation tables 339 in both hybrid nodes are preferably coordinated from the standpoint of using CIC. This typically means that in both hybrid nodes 330<sub>1</sub>/340<sub>1</sub> and 330<sub>2</sub>/340<sub>2</sub> a certain CIC points at the same VP and VC (and possibly AAL2 pointer) identifying cells on a certain physical link (e.g., link 341) connecting the two hybrid nodes. Alternatively, the same objective may be accomplished by other suitable means such as a cross-connected-ATM switch positioned between the hybrid nodes that switches packets and gives the packets the VP and VC value understood by the other node.

Referring now to FIG. 3A, an exemplary structure of hybrid STM/ATM network 320, having omitted therefrom various items including the interfaces, is illustrated.

-22-

FIG. 3A also provides an example of signal processing for a call originating at terminal 324<sub>O-P</sub> for which the called party number (destination) is terminal 324<sub>D-P</sub>. As shown by the arrow labeled E-1, at event E-1 a SETUP message is sent  
5 from terminal 324<sub>O-P</sub> to access node 322<sub>O</sub>. In the illustrated embodiment, the SETUP message is an IAM message for an ISUP network interface, and is for a 30B+D PRA and for VS.x carried on a 64 kb/s bit stream in a circuit switched timeslot.

10 At the translator 350<sub>O</sub> associated with the access node 322<sub>O</sub>, at event E-2 the signaling from terminal 324<sub>O-P</sub> is converted from STM to ATM by packing the signaling information into ATM cell(s). In this regard, after the circuit emulation a table is employed to translate from a  
15 64 kb/s speech channel from terminal 324<sub>O-P</sub> to a corresponding ATM address (VP/VC). The signaling of the SETUP message, now encapsulated in ATM cell(s), is applied to link 351<sub>O</sub> and transmitted to ATM cell switch 345 of ATM node 340<sub>1</sub> as indicated by event E-3. As further indicated  
20 by event E-4, the ATM cell(s) containing the SETUP message signaling is routed through the ATM cell switch 345 in accordance with a switch internal VP/VC dedicated for STM-originated signaling. Upon egress from ATM cell switch 345, the signaling information for the SETUP message is  
25 retrieved from the ATM cell(s) by translator 370 (event E-5), and it is reconverted at translator 370 from ATM to STM format, so that the SETUP message signaling information can be applied in STM format at event E-6 to switch-to-switch link 360. The SETUP message, now again in STM format, is  
30 routed through STM circuit switch 335 (as indicated by event E-7) to an appropriate one of the signaling terminals 337. Upon receipt of the SETUP message signaling information at the appropriate signaling terminal 337, the

-23-

signaling information is forwarded to processor(s) 332 of PSTN/ISDN node 330, which engage in STM traffic handling (as indicated by event E-8).

In its traffic handling, the processor 332 of  
5 PSTN/ISDN node 330 realizes that the incoming side of the call and the outgoing side of the call have physical connections through an ATM node. In this regard, when the access points of the connection were defined (subscriber or network interface), a bearer type was associated with the  
10 connection and stored in application software. In the present scenario, when the SETUP message (e.g., an IAM message in the case of an ISUP network interface) was received at PSTN/ISDN node 330, the stored bearer type data was checked in order to determine what switch was on the  
15 incoming side to PSTN/ISDN node 330. Further, the bearer type data stored for the outgoing point (e.g., based on B-Subscriber number) is similarly checked, and if the stored data indicates that both incoming and outgoing sides have an ATM bearer, the PSTN/ISDN node 330 can conclude that ATM  
20 node 340 is to be operated (e.g., utilized). In addition, data received in the SETUP message (particularly the B-subscriber number) is analyzed to determine that the called party (destination) terminal 324<sub>D-P</sub> can be reached by contacting PSTN/ISDN node 330<sub>2</sub>. The PSTN/ISDN node 330<sub>1</sub>  
25 realizes that it has an SS#7 signaling interface 300c to PSTN/ISDN node 330<sub>2</sub>, and therefore selects a free CIC (e.g., a CIC not used by any other call) for use toward PSTN/ISDN node 330<sub>2</sub>.

If, on the other hand, the stored bearer type data had  
30 indicated an STM bearer, both PSTN/ISDN node 330 and ATM node 340 have to be operated. Thus, PSTN/ISDN node 330 and ATM node 340 collectively function as a gateway between the STM and ATM worlds. Upon realizing that further signaling

-24-

for the call will be routed through ATM nodes, in the embodiment(s) of the invention shown in FIG. 3 and FIG. 3A, the PSTN/ISDN node 330<sub>1</sub> makes reference to an STM/GPN translation table 339 maintained by processor(s) 332 (see event E-9). Two translations are performed using the STM/GPN translation table 339. As a first translation, the information (e.g., b-channel and access information in the case of ISDN or CIC plus signaling system #7 point codes in the case of PSTN) contained in the SETUP message is translated to a global position number (GPN). As a second translation, the CIC and destination point code for a circuit leading to hybrid node pair 330/340 is translated to another global position number (GPN).

In connection with the foregoing, the global position number (GPN) is a common way to identify the connection points, and as such is understood by the pair of nodes (PSTN/ISDN node 330 and ATM node 340). In other words, the GPN is an address, or reference, or system internal pointer known by both PSTN/ISDN node 330 and ATM node 340, and used to translate between port/VP/VC and circuit switch address.

Usage of GPN in the embodiment of FIG. 3 and FIG. 3A thereby obviates the sending of real addresses between PSTN/ISDN node 330 and ATM node 340. Advantageously, GPN can be shorter, meaning that there is less data to send. For traditional PSTN, the GPN uniquely corresponds to the 64 kbit voice on a two-wire line, but for ISDN, the GPN corresponds to a b-channel (which may be used by several subscribers).

Then, as event E-10, the PSTN/ISDN node 330 generates an ATM switch control message intended to setup a physical connection in ATM node 340. This message of event E-10 contains the two global position numbers (GPNs) obtained from STM/GPN translation table 339 at event E-9, together

-25-

with an order for the ATM node 340 to connect the two GPN addresses in ATM switch fabric 345. The PSTN/ISDN node 330 sends the switch control message generated at event E-10 to processor 342 of ATM node 340 over interface 300a, as shown  
5 by event E-11.

Upon reception of the switch control message sent as event E-11 to ATM node 340<sub>1</sub>, as indicated by event E-12, main processor 342 consults GPN/ATM translation table 349 in order to translate the two global position numbers  
10 (GPNs) contained in the event E-10 switch control message into VP/VC/port information understood by ATM node 340<sub>1</sub>. That is, the two global position numbers (GPNs) are used to obtain VP/VC/port information for ultimately reaching both the origination terminal (324<sub>O-P</sub>) and the destination  
15 terminal (324<sub>D-P</sub>). Upon successful translation of GPN to ATM, and assuming sufficient resources, processor 342 of ATM node 340<sub>1</sub> sets up a path through ATM Switch 345 and reserves resources on the port (trunk or link 341) for the call from terminal 324<sub>O-P</sub> to terminal 324<sub>D-P</sub>. The path set  
20 up and resource reservation activities are accomplished using switch/reservation control 343 and are collectively illustrated as event E-13 in FIG. 3.

Since PSTN/ISDN node 330 preferably knows whether ATM node 340<sub>1</sub> was successful in performing a GPN/ATM  
25 translation, a successful translation message is sent over interface 300a as event E-14 from ATM node 340<sub>1</sub> to PSTN/ISDN node 330<sub>1</sub>. If the GPN/ATM translation is not successful at ATM node 340<sub>1</sub>, or if there are no available resources at ATM node 340<sub>1</sub>, a call rejection message is sent back to the  
30 originating terminal. After PSTN/ISDN node 330 receives the confirmatory message of event E-14 (that ATM switch 345 has been setup and link reservations made (in accordance with event E-13)), at event E-15 the PSTN/ISDN node 330<sub>1</sub>

-26-

prepares and sends its further signaling message (e.g., ISUP or TUP) toward the PSTN/ISDN node at the other end (e.g., PSTN/ISDN node 330<sub>2</sub>). This further signaling message is shown as event E-15 in FIG. 3A. The signaling of event  
5 E-15 (e.g., an ISUP or TUP message) includes a message transfer part (MTP), and can be sent out on a timeslot (e.g., 64 kb/s) which carries the SS#7 signaling.

As the signaling of event E-15 arrives at ATM node 340<sub>1</sub>, the ATM node 340<sub>1</sub> prepares its ATM cell-formatted  
10 version of the signaling. In particular, the translator 370 puts the signaling information of the signaling of event E-15 into the payload of one or more ATM cells. For example, the translator 370 is configured to take the 64 kb/s signaling information bit stream and to pack it into  
15 ATM cells with a predefined VP, VC, and a physical port.

As also indicated as event E-15, the ATM cell-formatted version of the further signaling message is routed through ATM cell switch 345 and onto a link indicated by the VP/VC/port information obtained from the translation. In  
20 particular, in FIG. 3A the ATM cell-formatted version of the further signaling message is transported on ATM physical link 341, as shown by event E-16.

Upon reaching ATM node 340<sub>2</sub>, the ATM cell-formatted version of the further signaling messages obtains a new  
25 internal VPI/VCI for the ATM cell switch 345 of ATM node 340<sub>2</sub>, and is routed (as indicated by event E-17) through ATM cell switch 345 of ATM node 340<sub>2</sub> to a circuit emulator (not explicitly shown) in ATM node 340<sub>2</sub>, which is analogous to circuit emulator 370 in ATM node 340<sub>1</sub>. The circuit emulator  
30 of ATM node 340<sub>2</sub> performs the conversion from ATM to STM format in like manner as circuit emulator 370 in ATM node 340<sub>1</sub>, and then passes the signaling message to PSTN/ISDN node 330<sub>2</sub> as event E-18.

-27-

In PSTN/ISDN node 330<sub>2</sub>, the ISUP message is received together with the CIC value (from the message transfer part (MTP)) and the B-subscriber number (which is included in the ISUP message). As indicated by event E-19, the second  
5 hybrid node 330<sub>2</sub>/340<sub>2</sub> also performs an analysis of the B-subscriber number and concludes that the B-subscriber number is associated with terminal 324<sub>D-P</sub>, which involves B channels. The PSTN/ISDN node 330<sub>2</sub> then selects a B-channel which can be used to reach terminal 324<sub>D-P</sub>, or negotiates  
10 with the terminal 324<sub>D-P</sub> as to which B-channel to use (depending on the terminal type and protocol type ISDN or PSTN). The PSTN/ISDN node 330<sub>2</sub> also signals terminal 324<sub>D-P</sub> to activate a ringing signal (as indicated by event E-20).

When an answer is received from terminal 324<sub>D-P</sub> (or during  
15 or before receiving an answer), the PSTN/ISDN node 330<sub>2</sub> consults its STM/GPN translation table 339 (not explicitly shown) using a CIC value and a B-channel. The PSTN/ISDN node 330<sub>2</sub> then operates the ATM switch 345 (not explicitly shown) of ATM node 340<sub>2</sub> in the same manner as described for  
20 ATM node 340<sub>1</sub>, as indicated by event E-21.

Operation of ATM switch 345 of ATM node 340<sub>2</sub> allows in-band data (e.g., voice data) carried in ATM packets to be passed through the ATM switch. Such operation is accomplished in like manner as described previously  
25 hereinabove (e.g., by consulting a table such as table 339, by sending an ATM switch control message, by consulting a table such as table 349, and by setting up of a path in the ATM switch). When an ATM switch is operated as described above, the resulting path through both ATM switches  
30 (carrying in-band information) has to be set up in the same way at both ends. This implies that encapsulation of in-band information (which is controlled by circuit emulation (e.g., circuit emulation 370)) at the two end points of the

-28-

path is preferably set up in the same way. To minimize delay, AAL2 is preferably utilized by circuit emulation 370 for the encapsulation, although other types of protocols may be alternatively used.

5 As noted hereinabove, a bearer type is associated with a connection and stored in the application software of the PSTN/ISDN node 330. It is presumed that the PSTN/ISDN node 330 already is able to handle traditional access points (subscriber or network interfaces) connected to STM circuit  
10 switches. In so doing, the PSTN/ISDN node 330 has logical representations of these existing access points in a static data structure of the PSTN/ISDN node 330. In accordance with certain embodiment(s) of the invention, the PSTN/ISDN node 330 additionally handles access points connected to  
15 the ATM switch. In this regard, see (for example) interface 341 of FIG. 3C (hereinafter described). Thus, for certain embodiment(s) of the invention, the PSTN/ISDN node 330 has logical representations of these additional access points in its static data structure. Therefore, the  
20 bearer type data may be employed in the prior discussion as a way of distinguishing the logical representation of the additional access points (e.g., ATM-related access points) in the static data structure from the logical representation of the traditional access points.

25 It was also noted hereinabove that encapsulation of in-band information is preferably set up the same way at both ends. More specifically, a same type of cell filling is preferably employed by two circuit emulation devices that are connected together. For example, if on a link  
30 connecting two circuit emulation devices an ATM cell is packed with only one voice sample by a first of the circuit emulation devices, the second of the circuit emulation devices preferably packs ATM cells in a similar manner.

-29-

Alternatively, another emulation and/or bridging mechanism or scheme may be employed.

In the above regard, filling only part of an ATM cell with information is a technique for reducing delays, although it may increase overhead. Another way of reducing delay is employment of the AAL2 protocol. As understood by those skilled in the art, AAL2 is a protocol layer on top of ATM, and it allows transport of mini-cells within ATM cells. Usage of the smaller AAL2 cells helps address bandwidth and delay problems in the air interface. Certain embodiment(s) of the invention may be utilized with AAL2 switching as an alternative to ATM switching. If one implements AAL2 in certain embodiment(s) of the invention, the switch 345 operates as an AAL2 switch and GPN/ATM translation table 349 in ATM node 340 preferably also includes an AAL2 pointer. Whenever the ingress and egress point is referenced, it can alternately include an AAL2 pointer. Thus, as used herein and in the appended claims, ATM encompasses ATM-related protocols on top of ATM, such as AAL2. It should also be understood that the term "broadband", as used herein and in the appended claims, embraces and encompasses packet-switched technologies in general (e.g., IP, VoIP, Frame-relay, ATM, etc.).

Referring now to FIG. 3B, an exemplary hybrid STM/ATM network 320' according to another embodiment of the invention is illustrated. The embodiment of FIG. 3B primarily differs from the embodiment of FIG. 3 in that the embodiment of FIG. 3B does not employ global position numbers (GPNs). Rather, the embodiment of FIG. 3B uses an ATM/STM translation table 339' in processor 332 of PSTN/ISDN node 330<sub>1</sub> instead of an GPN/ATM translation table.

In the embodiment of FIG. 3B, the translation tables in the circuit emulation 350<sub>0</sub> translate the SETUP message from

-30-

a 64 kb/s speech channel to an ATM address (VP and VC) in a manner similar to that of event E-2 in the embodiment(s) of FIG. 3 and FIG. 3A. After routing of the translated SETUP message through ATM switch 345<sub>1</sub>, the circuit emulation  
5 370 translates the SETUP message to the STM format as occurred at event E-5 of the embodiment(s) of FIG. 3 and FIG. 3A.

The embodiment of FIG. 3B also differs from that of the embodiment(s) of FIG. 3 and FIG. 3A in that processor  
10 332 of PSTN/ISDN node 330 terminates the narrowband signaling by translating a narrowband reference point (e.g., b-channel if an ISDN connection) to a corresponding ATM address for use by ATM node 340. Thus, for the FIG. 3B embodiment, the switch control message of event E-11 sends  
15 the ATM VP/VC/port information understood by ATM node 340<sub>1</sub>.

Thus, the translation of event E-12 of the FIG. 3/FIG. 3A embodiment is unnecessary in the FIG. 3B embodiment. Rather, upon receiving the ATM VP/VC/port information in the switch control message of event E-11, the embodiment of  
20 FIG. 3B proceeds to the path set up and resource reservation operations denoted as event E-13.

The principles as illustrated in the embodiments hereof are also applicable to the carrying of other types of signaling messages in ATM cells. Included among such  
25 other types of signaling messages are those destined for the originating terminal (e.g., a call completion signaling message), in which case some of the events described herein are performed essentially in reverse order.

Referring now to FIG. 3C, an exemplary illustration of  
30 how hybrid node pairs 330/340 of the invention may be arranged in an exemplary hybrid STM/ATM network 320" is presented. Network 320" has three node pairs 330/340, including a transit exchange hybrid node pair 330/340<sub>TX</sub>

between two local exchange hybrid node pairs 330/340<sub>1</sub> and 330/340<sub>2</sub>. FIG. 3C shows provision of a "#7 signaling system" 393, which is a logical system carried in the ATM network on an ATM AAL layer as described above. As an  
5 alternative embodiment, the "#7 signaling system" 393 may be provided with its own physical network.

Referring now to FIG. 3D, a diagrammatic view of an exemplary protocol usable between two elements of a network in accordance with embodiment(s) of the invention that  
10 include hybrid node pairs is illustrated. The ATM node 340 with its ATM switch 345 terminates the ATM and AAL1 (circuit emulation part) layers; the PSTN/ISDN node 330 terminates the MTP and ISUP layers.

Referring now to FIGS. 3E, 3F, and 3G, diagrammatic  
15 views of alternate exemplary protocols between two elements, a first of the network elements having a hybrid node pair in accordance with embodiment(s) of the invention, and a second of the network elements being an access node with an additional ATM interface with circuit  
20 emulation is illustrated. In the first network element, the ATM switch 345 terminates the ATM and AAL1 (circuit emulation part) layers, while the layers above are terminated by the PSTN/ISDN node 330. In the second network element, the ATM interface and circuit emulation  
25 addition to the access node terminates the ATM and AAL1 layers, while the layers above are terminated by the connected terminal and the access node part. The exemplary protocols of FIGS. 3E, 3F, and 3G can be used, for example, on the interface 300b.

30 Referring now to FIG. 3H, an exemplary gradual upgrade of a network from a traditional narrowband STM-transported-and-switched environment into the environment (e.g., hybrid STM/ATM network 320) of certain embodiment(s) of the

-32-

invention is illustrated. In FIG. 3H, the circuit emulation equipment (translator) 395 separates the hybrid environment from the pure STM environment. If node B (PSTN/ISDN node 330<sub>N+1</sub>) is upgraded with ATM switching and (signaling and traffic) transport according to certain embodiment(s) of the invention, the node C (PSTN/ISDN node 330<sub>N+2</sub>) is not disturbed if the circuit emulation equipment (translator) 395 is moved in between nodes B and C in the manner illustrated by the dotted-dashed line 396 as shown in FIG. 3H.

Referring now to FIG. 3I, certain embodiment(s) of the invention permit the possibility of one logical node to include many switches, with switching logic within the node coordinating the setting up of paths through the switches. This logic also inserts interworking functions (IWFs) between switches (if needed), and makes it possible to use resources independent on which switch they are allocated to. For example, the multi-switch node 397 of certain embodiment(s) of the invention includes the PSTN/ISDN node 330 with its STM switch 335, connected by interface 300d to ATM node 340<sub>7-1</sub>. Specifically, connection is made through IWF 344<sub>7-1</sub> to ATM switch 345<sub>7-1</sub> of ATM node 340<sub>7-1</sub>. The ATM switch 345<sub>7-1</sub> of ATM node 340<sub>7-1</sub> is connected by interface 300e to an ATM network, as well as to ATM node 340<sub>7-2</sub> and ATM node 340<sub>7-3</sub> included in the multi-switch node 397. The ATM node 340<sub>7-2</sub> has a switch 345<sub>7-2</sub> and an IWF 344<sub>7-2</sub>, through which connection can be made with access node 322<sub>7-1</sub>. The ATM node 340<sub>7-3</sub> has an ATM AAL2 switch 345<sub>7-3</sub>, which connects to ATM nodes 340<sub>7-1</sub> and 340<sub>7-2</sub> through IWF 344<sub>7-3</sub> of ATM node 340<sub>7-3</sub>. Access nodes 322<sub>7-2</sub> and 322<sub>7-3</sub> are connected to ATM AAL2 switch 345<sub>7-3</sub> of ATM node 340<sub>7-3</sub>.

Certain embodiment(s) of the invention advantageously reuse PSTN and ISDN software in the PSTN/ISDN nodes 330 in

-33-

a fairly simple way. That is, already-developed narrowband application software residing in the PSTN/ISDN nodes 330 can be utilized, while on-demand ATM connections are used as traffic bearers. The invention thus allows a PSTN/ISDN node such as PSTN/ISDN node 330 to control the call, which facilitates use of well-proven software for various services and functions (e.g., subscriber services, intelligent network (IN) services, Centrex, Charging Customer Care systems, etc.).

10 ATM is thus used as a transport and switching mechanism in certain embodiment(s) of the invention, while the signaling remains normal narrowband signaling. The narrowband signaling is transported on permanent paths over ATM connections, and the narrowband speech channels are transported on ATM, and switched on a "per call basis" (e.g., on-demand) through an ATM switch.

The narrowband application software executed by processor(s) 332 of PSTN/ISDN nodes 330 thus acts as if operating on its STM circuit switched transport, when in fact it is actually operating on an ATM cell switch. It should be understood that the ATM switch may reside in a separate ATM node or may be integrated in the same node as the STM switch. On a "per call basis", the switching logic in the PSTN/ISDN nodes 330 requests the switching logic in the ATM nodes 340 to be set up and disconnected through an ATM cell switch.

25 It should be understood that variations of the foregoing are within the scope of the embodiments of the invention. For example, the circuit emulation 370 is shown (e.g., in FIG. 3) as being provided on a device board of ATM node 340. Alternatively, circuit emulation 370 may be located elsewhere, such as (for example) on link 360 between PSTN/ISDN node 330 and ATM node 340, or even

-34-

included in PSTN/ISDN node 330 (e.g., at either end of interface 300d). While various processors, such as processors 332 and 342, have been illustrated as single processors, it should be understood that the functionality  
5 of such processors may be situated or distributed in different ways (e.g., distributed over several processors to achieve, e.g., scalability in respect to processing capacity and reliability), for example.

In the foregoing examples, the SETUP message (received at the STM node in STM format) is routed through STM circuit switch 335 as indicated by the event E-8 to signaling terminals 337. It should be understood, however, that depending upon implementation in an PSTN/ISDN node, signaling may take another way to reach a signaling terminal (e.g., other than through a switch). The invention also describes a system with one STM switch and one ATM switch associated with one another. This particular configuration is advantageous in that resources which take care of certain kinds of signals (e.g., in-band signals) may be situated in the STM switch and be used also for the ATM transported calls. This is also a way of reusing the installed base, if such exists. Also, certain embodiment(s) of the invention can perform switching on various levels, such as the AAL2 level and with mini-cells, which tends to reduce any delay/echo problems.

The invention thus pertains to the telecommunications world and an attempt to introduce ATM to a telecommunications network. The invention addresses the situation in which a circuit switched telephony network pre-exists, and it is to be augmented or partially replaced by parts that employ ATM for transport and switching. Certain embodiment(s) of the invention need not employ broadband signaling, but rather narrowband signaling with the bearer part of the call following the signaling to the same extent as in a traditional narrowband circuit switched network.

As described herein, ATM may be used as a transport and switching mechanism in a hybrid STM/ATM network, while the signaling remains normal narrowband signaling. The narrowband signaling may be transported on permanent paths over ATM connections, and the narrowband speech channels

-36-

may be transported on ATM and switched on a "per call basis" (e.g., on-demand) through an ATM switch. The hybrid STM/ATM network may include an access node that services narrowband terminals and which generates a signaling message in connection with call setup. A translator formats the first signaling message into ATM cells so that the first signaling message may be routed through an ATM switch to a circuit switched (e.g., STM) node. The circuit switched node (e.g., PSTN/ISDN) sets up a physical connection for the call and generates a further signaling message for the call, the further signaling message pertaining to the physical connection. The ATM switch routes an ATM cell-formatted version of the further signaling message to another ATM switch over an ATM physical interface. Thus, the ATM switch switches both narrowband traffic and signaling for the call over the ATM physical interface.

Referring now to FIG. 4, another exemplary scheme for utilizing a broadband network in conjunction with nodes having partially separated functions in accordance with the present invention is illustrated generally at 400. The nodes 405A,405B are connected to the nodes 410A,410B. The nodes 405A,405B each include both call control functions and connection control functions. In effect, each of the nodes 405A,405B (e.g., which may correspond to, for example, PSTN/ISDN nodes 330 of the embodiment(s) of FIGS. 3 et seq.) include both switching intelligence (e.g., which may correspond to, for example, one or more of processor(s) 332, switch and resource control software 333, signaling terminals 337, and STM/GPN translation table 339 of the embodiment(s) of FIGS. 3 et seq.) and switching fabric (e.g., which may correspond to, for example, an STM circuit switch 335 of the embodiment(s) of FIGS. 3 et seq.). While

-37-

the nodes 410A,410B include connection control functions, they rely on the call control functions of the nodes 405A,405B to which they are respectively connected. In effect, each of the nodes 410A,410B (e.g., which may correspond to, for example, ATM nodes 340 of the embodiment(s) of FIGS. 3 et seq.) include switching fabric (e.g., which may correspond to, for example, an ATM cell switch 345 of the embodiment(s) of FIGS. 3 et seq.). The nodes 410A,410B, which are also connected to an ATM network 215, effect required emulation and cell packing for interworking a narrowband network (not shown) with the ATM network 215.

Generally, and in certain embodiment(s), call control involves features, functions, responsibilities, etc. pertaining to one or more of the following: routing a call; signaling between narrowband nodes; providing subscriber services; implementing charging; determining the connection and/or activation of tone senders, answering machines (e.g., voice mail), echo cancelers, and other types of telephony resources and/or equipment; ascertaining the desirability and/or necessity of utilizing an IN service; etc. Connection control, on the other hand, involves features, functions, responsibilities, etc. pertaining to setting up/establishing a connection between two (or among/across multiple) physical points within a switch and/or over a network responsive to call control, for example. The connection control, to effectuate such a connection, may rely on some type of signaling of the bearer network (e.g., UNI, PNNI, B-ISUP, etc.)

In accordance with certain embodiment(s) of the present invention, the nodes 405A,405B may be advantageously realized using, at least partly, a modified version of an existing telecommunications switch. Using an

-38-

existing telecommunications switch advantageously obviates any need to create code "from scratch" for the myriad of advanced calling features that are already supported by the existing telecommunications switch. Furthermore, in accordance with certain principles of the present invention, using an existing telecommunications switch enables a gradual migration to a broadband transport mechanism such as ATM. A call/connection control node 405A, 405B and a respective connection control node 410A, 410B pair together form a hybrid switch 420A/420B.

Referring now to FIG. 5, yet another exemplary scheme for utilizing a broadband network in conjunction with nodes having partially separated functions in accordance with the present invention is illustrated generally at 500. The two hybrid switches 420A, 420B are illustrated as being connected to the ATM network 215 by ATM links 505 (e.g., which may correspond to, for example, one or more of interface 300c, interface 300e, and ATM physical link 341 of the embodiment(s) of FIGS. 3 et seq.), e.g., via a connection control node 410. Each of the call/connection control node 405A and the connection control node 410A are connected to a Time Division Multiplexed (TDM) network 515 by TDM links 510 (e.g., which may correspond to, for example, interface 300d of embodiment(s) of FIGS. 3 et seq. [including alternative embodiment(s) of FIGS. 3 et seq. as described hereinabove with reference to the interface 300d of FIG. 3]; as well as interface 300b/link 351, interfaces 300b, 300c, and/or interface 300d/switch-to-switch link 360). The TDM network 515 may correspond to any of many so-called narrowband networks such as PSTN, PLMN, ISDN, etc. As indicated within the hybrid switch 420A, the call/connection control node 405A is connected to the connection control node 410A via a TDM link 510 (e.g.,

which may correspond to, for example, interface 300b, interface 300c, interface 300d, switch-to-switch link 360, etc. of FIGS. 3 et seq.) and an ethernet link 520 (e.g., which may correspond to, for example, interface 300a, interface 300b, interface 300c, switch-to-switch link 360, etc. of FIGS. 3 et seq.).

The hybrid switch 420 advantageously enables an existing switch in conjunction with an associated switch to facilitate the transport of call connections at least partly across a broadband network, such as the ATM network 215. As illustrated in the scheme 500, the existing switch may be realized using, for example, an AXE switch (available from Ericsson Inc.), and the associated switch may be realized using, for example, an AXD 301 switch (also available from Ericsson Inc.). Thus, the hybrid switches 420A, 420B may be realized using, for example, an Ericsson Hybrid Switch (also available from Ericsson Inc.).

Referring now to FIG. 6, another exemplary hybrid switch with multiple ports for switching a connection in accordance with the present invention is illustrated generally at 420. The hybrid switch 420 includes a call/connection control node 405 and a connection control node 410 that are connected by linkage 605 (e.g., which may correspond to, for example, one or more of interface 300a, interface 300b, interface 300c, interface 300d, and switch-to-switch link 360 of the embodiment(s) of FIGS. 3 et seq.). It should be noted that the thick line representing the linkage 605 indicates that the linkage 605 may be composed of more than one link. Information exchange across linkage 605 permits the call/connection control node 405 to switch narrowband calls across the switching fabric of the connection control node 410. Such information exchange enables 64kbit/sec, narrowband calls originating

-40-

and terminating in narrowband networks (e.g., one or more TDM networks 515) to be trunked over broadband networks (e.g., one or more ATM networks 215) between hybrid switches 420. It should be noted that TDM as used herein, including the claims, encompasses and embraces time-division multiplexed protocols in general, and it is not limited to any particular TDM protocol.

The call/connection control node 405 includes input/outputs (I/Os) for two TDM links 510. Each TDM link 510 terminates at exchange termination (ET) equipment 610. Each ET equipment 610 is connected to a group switch (GS) 615 (e.g., which may correspond to, for example, the STM circuit switch 335 of the embodiment(s) of FIGS. 3 et seq.). Each ET equipment 610 receives from the GS 615 data samples taken from multiple calls and multiplexes this data into a stream of data sent out over a TDM link 510 that connects the hybrid switch 410 to another node. The ET equipment 610 also receives data from other nodes over the TDM link 510 and de-multiplexes this data into samples from separate calls to be transferred to the GS 615. The GS 615 is also connected to one or more signaling terminals (STs) 620 (e.g., which may correspond to, for example, the signaling terminals 337 of the embodiment(s) of FIGS. 3 et seq.). The linkage 605 may include a TDM link 510 (not explicitly shown in FIG. 6) that connects an ET equipment 610 of the call/connection control node 405 with a circuit emulation-ET (CE-ET) equipment 625 (e.g., which may correspond to, for example, the circuit emulation/translator 370 of the embodiment(s) of FIGS. 3 et seq.) of the connection control node 410.

The connection control node 410 includes I/Os for two TDM links 510. Each TDM link 510 terminates at CE-ET equipment 625 (e.g., which may correspond to, for example,

-41-

the extension terminal ET 346<sub>2</sub> (optionally in conjunction with the circuit emulation/translator 350) of the embodiment(s) of FIGS. 3 et seq.). Each CE-ET equipment 625 is connected to an ATM switch 630 (e.g., which may correspond to, for example, the ATM switch 345 of the embodiment(s) of FIGS. 3 et seq.). The CE-ET equipment 625 terminates a TDM link 510 for the ATM switching fabric of the connection control node 410 by using circuit emulation.

The circuit emulation, e.g., hardware on a CE-ET equipment 625 maps time slots from an E1 line into, for example, single streams of ATM adaptation layer 1 (AAL1) cells. The CE-ET equipment 625 maps successive octets from a single time slot to a single stream of AAL1 cells. The ATM switch 630 is also connected to one or more ATM-ET equipments 635 (e.g., which may correspond to, for example, the extension terminal ET 346<sub>1</sub> of the embodiment(s) of FIGS. 3 et seq.).

Each ATM-ET equipment 635 terminates an ATM link 505 to the ATM switching fabric of the connection control node 410.

The various ports/interfaces of the call/connection control node 405 and the connection control node 410 enable the establishment of various connection paths in the hybrid switch 420. Connection paths may be established across the following exemplary points as enumerated in Table 1:

25

|                          |
|--------------------------|
| (1) point A - (I, J) - G |
| (2) point A - (I, J) - H |
| (3) point D - (J, I) - B |
|                          |

|                           |
|---------------------------|
| (4) point E - (J, I) - B  |
| (5) point C - (I, J) - G  |
| (6) point C - (I, J) - H  |
| (7) point D - (J, I) - F  |
| (8) point D - G           |
| (9) point D - H           |
| (10) point E - (J, I) - F |
| (11) point E - G          |
| (12) point E - H          |

Table 1 -- Connection Paths Establishable for FIG. 6. Taking connection path "(6) point C - (I, J) - H", for example, a connection may be established from point "C" at the TDM link 510, through two ET equipments 610 and the GS 615, to point "I". The connection continues from point "I" across the linkage 605 to point "J". The connection continues further from point "J" through a CE-ET equipment 625, the ATM switch 630, and the ATM-ET equipment 635 to point "H" at the ATM link 505.

Referring now to FIG. 7, a simplified block diagram of an exemplary hybrid switch in accordance with the present invention is illustrated generally at 700. The hybrid switch at 700 includes a call/connection control node 405,

-43-

which is shown connected to a TDM network 515 via a TDM link 510, and a connection control node 410, which is shown connected to a TDM network 515 via a TDM link 510 and an ATM network 215 via an ATM link 505. The call/connection control node 405 is connected to the connection control node 410 via the linkage 605, which may include one or more links. The connection control node 410 includes connection control logic 705 and the ATM switch 630. The connection control logic 705 may be composed of, for example, hardware, software, firmware, some combination thereof, etc.

The ATM switch 630 is connected via link 710 to the GS 615 of the call/connection control node 405. The link 710 may be utilized to transfer data information between the ATM switch 630 and the GS 615. The call/connection control node 405 also includes connection control logic 715 to enable the call/connection control node 405 to switch calls (e.g., to or through the TDM network 515 directly connected thereto via the TDM link 510) without the aid of the connection control node 410. The connection control logic 715 may also be composed of, for example, hardware, software, firmware, some combination thereof, etc. The call/connection control node 405 further includes call control logic 720, which provides call control functions for the connection control node 410 as well as the call/connection control node 405. The call control logic 720 may also be composed of, for example, hardware, software, firmware, some combination thereof, etc.

The call control logic 720 may provide call control functions to the connection control node 410 by exchanging signaling information over a link 725. (It should be noted that either or both of the links 710 and 725 may be composed of more than one link.) For example, for a call

-44-

incoming to the connection control node 410 over the TDM link 510 from the TDM network 515, signaling information may be forwarded to the call control logic 720 from the connection control logic 705 over the link 725. The  
5 switching intelligence of the call control logic 720 executes applicable call control functions and ascertains relevant call control information (e.g., as explained further hereinabove with reference to FIGS. 3 et seq.). This signaling information is sent from the call control  
10 logic 720 over the link 725 to the connection control logic 705, which may thereafter switch the call data information of the incoming call to/through the appropriate network (e.g., the ATM network 215). The call control functions of existing (e.g., STM) switches can therefore be  
15 advantageously utilized by newer and faster (e.g., ATM) switches to thereby avoid needing to completely reprogram call control functionality for the newer switches.

It should be emphasized that the call/connection control node 405 is capable of connecting directly to the  
20 TDM network 515 over the TDM link 510 via the GS 615. Consequently, a hybrid switch architecture in accordance with the present invention, by combining a call/connection control node 405 with a connection control node 410, enables this logical node to communicate (i) with an  
25 existing TDM network 515 (e.g., a PSTN network) using the GS 615 (e.g., an STM switch) and (ii) with a broadband network (e.g., the ATM network 215) over a broadband link (e.g., the ATM link 505) using a broadband switch (e.g., the ATM switch 630). Providing such dual connectivity  
30 advantageously enables a network to gradually migrate from a first network protocol (e.g., a narrowband network protocol) to a second network protocol (e.g., a broadband network protocol) while utilizing both existing call

control logic (e.g., software, etc.) and existing connections to and within the first network (e.g., a narrowband network).

Referring now to FIG. 8, exemplary communications and connections between nodes in another simplified block diagram of an exemplary hybrid switch in accordance with the present invention are illustrated generally at 800. In the exemplary hybrid switch 420, the call/connection control node 405 is connected to the connection control node 410 via the linkage 605 at points I and J. The linkage 605 may be composed of multiple links. In this exemplary embodiment 800, a signaling information link 805 (e.g., which may correspond to, for example, interface 300a, interface 300b, interface 300c, switch-to-switch link 360, etc. of FIGS. 3 et seq.) and a data information link 810 (e.g., which may correspond to, for example, interface 300b, interface 300c, interface 300d, switch-to-switch link 360, etc. of FIGS. 3 et seq.) are illustrated as connecting the call/connection control node 405 to the connection control node 410. The signaling information link 805 may carry signaling communications between the call/connection control node 405 and the connection control node 410, and the data information link may carry data communications between the call/connection control node 405 and the connection control node 410. Such data communications may include voice or data calls, for example.

In an exemplary embodiment, the signaling information link 805 is realized using two ethernet links. One ethernet link may be used for transmitting signaling information from the call/connection control node 405 to the connection control node 410 while the other ethernet link may be used for transmitting signaling information from the connection control node 410 to the call/connection

-46-

control node 405. It should be understood that ethernet links are typically duplex in nature and that any ethernet links employed in any particular embodiment(s) in accordance with the present invention may also be duplex.

5 The data information link 810 may be realized using a TDM link. For example, the data information link 810 may be composed of one or more E1 lines. Communications necessary and/or beneficial to establishing the various connections described hereinabove with reference to FIGS. 6 and 7, for  
10 example, may be effectuated across the signaling information link 805 and the data information link 810. Advantageously, because separate links are employed between the nodes 405 and 410, signaling information and data information may be transferred therebetween across links  
15 805 and 810, respectively, without needing to specify whether the transmitted information pertains to signaling or to data.

As illustrated generally at 800, the call/connection control node 405 is connected to two TDM networks 515, and  
20 the connection control node 410 is connected to two TDM networks 515 as well as two ATM networks 215. It should be noted that the number of networks to which the nodes 405 and 410 are connected is exemplary only. The flexibility of the hybrid node 420 advantageously enables calls to be  
25 incoming at either of the nodes 405 and 410 and to be forwarded via a connection of either of the nodes 405 and 410. In other words, a narrowband call incoming to the connection control node 410 (at point D) or a broadband call (e.g., a narrowband call being carried by a broadband  
30 transport mechanism, etc.) incoming to the connection control node 410 (at point E) may be forwarded from the connection control node 410 (as a narrowband or broadband call at point G or point H, respectively) or from the

-47-

call/connection control node 405 as a narrowband call (e.g., at point F). Furthermore, a narrowband call incoming to the call/connection control node 405 (at point C) may be forwarded from the call/connection control node 5 405 as a narrowband call (at point F) or from the connection control node 410 (e.g., as a narrowband or broadband call at point G or point H, respectively). It should be noted that other combinations of ingress and egress (e.g., other connection paths) are possible.

10 By way of a first example but not limitation, assume that a call (or, more generally, a communication) is incoming to the connection control node 410 from a TDM network 515 at point D. The signaling information related to the call (e.g., an ISUP Initial Address Message (IAM)) 15 is encapsulated into ATM cells (e.g., at the CE-ET equipment 625 at point D) and passed to the ATM switch 630. Advantageously, the signaling information may therefore be piped through the connection control node 410 and over the (e.g., ethernet-based) signaling information link 805 20 without reformatting after being de-packaged from ATM cells (e.g., at the CE-ET equipment 625 at point J). The signaling information therefore need not be modified inasmuch as it may be transported through "transparent" pipes across the ATM switching fabric of the connection 25 control node 410 (e.g., using a permanent virtual path connection (PVPC) pipe or similar, etc.).

When the GS 615 and associated call control logic (not explicitly shown in FIG. 8) receive the signaling information of the incoming call, the signaling information 30 is analyzed (e.g., by an ST 620 at point A or point B). The traffic call handling is performed by, for example, performing a B-number analysis, accessing an interactive voice response system, contacting an Intelligence Network

-48-

(IN) node 815 (e.g., for "(800)" call routing, etc.), consulting a database of bearer capabilities for destination and/or transit nodes, etc. If, in contradistinction to the example described hereinabove with reference to FIG. 3A, the call/connection control node 405 determines that the call should not or can not be routed through a broadband ATM transport mechanism, then the call/connection control node 405 instructs the connection control node 410 (e.g., over the signaling information link 805) to route the data information of the call to (and through) the call/connection control node 405.

The data information of the call is routed through the connection control node 410 from point D to point J (e.g., by piping the data information via a semi-permanent connection through the switching fabric of the ATM switch 630). It should be noted that the data information may be propagated through the connection control node 410 without reformatting by, for example, encapsulating the data information in ATM cells. Thereafter, the data information is forwarded from point J to point I over the data information link 810 in, for example, a TDM format. The ET equipment 610 receives the data information of the call, and the GS 615 switches it toward the appropriate TDM network 515 (e.g., through an ET equipment 610 to a point C or a point F) in accordance with the earlier traffic call analysis.

By way of a second example but not limitation, assume that a call is incoming to the call/connection control node 405 from a TDM network 515 at point C. The call/connection control node 405 performs a traffic call analysis based on signaling information of the call. If the analysis indicates that the call can (and optionally should) be sent over a broadband transport mechanism, the call/connection

control node 405 can direct the incoming call through the connection control node 410 and then to an ATM network 215, instead of directing the call to a TDM node in a TDM network 515 (e.g., through the ET equipment 610 at the point F). In this regard, the GS 615 may switch the call signaling information to the ATM switch 630 via the signaling information link 805 and the call data information to the ATM switch 630 via the data information link 810 (and appropriate ET equipment 610 and CE-ET equipment 625 at point I and point J, respectively). The ATM switch 630 may thereafter send the signaling information of the call over permanent connections set up in the broadband ATM network 215 and the data information of the call over, e.g., call-specific connections in the broadband ATM network 215 (via an ATM-ET equipment 635 at point E or point H).

Referring now to FIG. 9, an exemplary method in flowchart form for communicating between nodes in a hybrid switch in accordance with the present invention is illustrated generally at 900. In the exemplary method of flowchart 900, an incoming call is initially received at a first node (step 905). The first node sends signaling information related to the incoming call to a second node via a first link (step 910). The second node, which may provide call control for the first node, processes the signaling information (step 915) to determine how and to where the incoming call is to be routed. The second node sends instructions to the first node (e.g., via the first link) (step 920) directing the first node on how/where to route the incoming call. Assuming that the second node determined that the incoming call should be routed as an outgoing call from the second node (at step 915) and that the instructions sent to the first node (at step 920) so

-50-

indicated, data information related to the incoming call is sent from the first node to the second node via a second link (step 925).

Alternatively, an incoming call can be received at a  
5 node capable of processing the corresponding signaling information. Accordingly, both signaling information and data information corresponding to the incoming call may be sent to an associated node via first and second links, respectively, if the node receiving the incoming call  
10 determines that it is appropriate to do so (e.g., as described hereinabove in the second example referencing FIG. 8). The call control functions of existing (e.g., STM) switches can therefore be advantageously utilized by newer and faster (e.g., ATM) switches to thereby avoid  
15 needing to completely reprogram the call control functionality for the newer switches. Furthermore, hybrid switches including both narrowband and broadband switches enable greater versatility for switching communications between broadband and narrowband transport mechanisms.

20 Although preferred embodiment(s) of the methods, systems, and arrangements of the present invention have been illustrated in the accompanying Drawings and described in the foregoing Detailed Description, it will be understood that the present invention is not limited to the  
25 embodiment(s) disclosed, but is capable of numerous rearrangements, modifications, and substitutions without departing from the spirit and scope of the present invention as set forth and defined by the following claims.

**WHAT IS CLAIMED IS:**

1. An arrangement for combining narrowband and broadband transport mechanisms in a communications network, comprising:

5 a first node, said first node configured to provide call control functions;

a second node, said second node connected to said first node by at least one link, said second node configured to provide connection control functions, said  
10 second node adapted to rely on said first node for call control functions; and

wherein data information and signaling information are transmitted over the at least one link.

15 2. The arrangement according to claim 1, wherein the at least one link comprises a first link and a second link, and whereby the data information is transmitted over the first link, and the signaling information is transmitted over the second link.

20

3. The arrangement according to claim 2, wherein the first link comprises a time division multiplexed (TDM) link, and the second link comprises an ethernet link.

25

4. The arrangement according to claim 2, wherein the at least one link further comprises a third link, and whereby the signaling information is also transmitted over the third link, the signaling information being transmitted from said first node to said second node over the second  
30 link and from said second node to said first node over the third link.

-52-

5. The arrangement according to claim 2, wherein neither the data information nor the signaling information is identified as such.

5 6. The arrangement according to claim 1, wherein said first node is further configured to provide connection control functions and is adapted to route a communication incoming to said second node as an outgoing communication from said first node by directing the communication over  
10 the at least one link, the communication including data information.

7. The arrangement according to claim 1, wherein said first node is further connected to a first time  
15 division multiplexed (TDM) network, and said second node is further connected to a second TDM network and an asynchronous transfer mode (ATM) network.

8. The arrangement according to claim 1, wherein  
20 said first node includes a synchronous transfer mode (STM) switch, and said second node includes an asynchronous transfer mode (ATM) switch.

9. The arrangement according to claim 1, wherein  
25 call control functions comprise switching intelligence of a telecommunications node, and connection control functions comprise switching fabric of a telecommunications node.

10. A dual-node system for combining narrowband and  
30 broadband transport mechanisms in a communications network, comprising:

a first node, said first node configured to provide call control functions;

-53-

a second node, said second node connected to said first node by at least one link, said second node configured to provide connection control functions and adapted to transmit data information and signaling information over the at least one link; and

wherein said first node and said second node function as a single logical node within the communications network.

10 11. The dual-node system according to claim 10, wherein the at least one link comprises a first link and a second link, and whereby the data information is transmitted over the first link, and the signaling information is transmitted over the second link.

15

12. The dual-node system according to claim 10, wherein an incoming communication to said second node over a broadband transport mechanism is forwarded from the single logical node as an outgoing communication from said first node over a narrowband transport mechanism responsive to a traffic determination made by said first node.

20

13. The dual-node system according to claim 10, wherein the single logical node comprises a hybrid switch.

25

14. A telecommunications system comprising:

a first node, said first node configured to provide call control functions;

a second node, said second node configured to provide connection control functions and capable of receiving telecommunications data, said second node adapted to rely on said first node for call control functions;

30

a first link for connecting said first node with said second node, said first link for transporting signaling information associated with the received telecommunications data between said second node and said first node; and

a second link for connecting said first node with said second node, said second link for transporting the received telecommunications data between said first node and said second node.

10

15. The telecommunications system according to claim 14, further comprising a third link, said third link for connecting said first node with said second node, said third link for transporting call control information from said first node to said second node for controlling the received telecommunications data; and wherein said first link is for transporting the signaling information associated with the received telecommunications data from said second node to said first node.

20

16. The telecommunications system according to claim 14, wherein said first node is further connected to an intelligent network (IN) node, and said second node is further connected to a time division multiplexed (TDM) network and an asynchronous transfer mode (ATM) network.

25

17. A telecommunications arrangement comprising:

a control node for providing call control instructions;

30

another node for receiving telecommunications data and relying on the call control instructions received from the control node to route the received telecommunications data;

-55-

a signaling link for communicating signaling information associated with the received telecommunications data from said another node to said control node; and

a call control link for communicating at least one call control instruction from said control node to said another node, the at least one call control instruction generated as a result of processing the communicated signaling information.

10 18. The telecommunications arrangement according to claim 17, wherein said another node comprises at least one of an access node and a broadband switching node.

15 19. The telecommunications arrangement according to claim 17, further comprising:

a data link for communicating the received telecommunications data between said another node and said control node.

20 20. A method for combining narrowband and broadband transport mechanisms in a communications network, comprising the steps of:

providing a first node having call control functionality;

25 providing a second node having connection control functionality;

sharing, by the first node, the call control functionality with the second node;

30 transmitting, by the second node, data information related to a communication to the first node; and

transmitting, by the second node, signaling information related to the communication to the first node.

21. The method according to claim 20, wherein said step of transmitting, by the second node, signaling information related to the communication to the first node  
5 comprises the step of:

        piping the signaling information through the second node and from the second node to the first node without reformatting.

10 22. The method according to claim 20, further comprising the steps of:

        receiving, by the first node, the signaling information related to the communication from the second node;

15          analyzing, by the first node, the signaling information related to the communication to make a traffic routing determination; and

        transmitting, by the first node, a routing instruction that is based on the traffic routing  
20 determination to the second node.

23. The method according to claim 20, wherein said step of transmitting, by the second node, data information related to a communication to the first node comprises the  
25 step of transmitting, by the second node, the data information related to the communication to the first node via a first link and said step of transmitting, by the second node, signaling information related to the communication to the first node comprises the step of  
30 transmitting, by the second node, the signaling information related to the communication to the first node via a second link.

-57-

24. The method according to claim 20, wherein said step of transmitting, by the second node, data information related to a communication to the first node comprises the step of:

5           transmitting, by the second node, the data information related to the communication to the first node without indicating whether the transmitted information corresponds to data information or signaling information.

10          25. A method for combining narrowband and broadband transport mechanisms in a communications network, comprising the steps of:

            receiving, at a first node, a communication, the communication including data information and signaling  
15 information;

            sending, by the first node, the signaling information to a second node;

            processing, by the second node, the signaling information to produce at least one routing instruction;

20           sending, by the second node, the at least one routing instruction to the first node; and

            sending, by the first node, the data information to the second node responsive to the at least one routing instruction.

25

26. The method according to claim 25, further comprising the step of:

            forwarding, by the second node, the communication to another node.

30

27. The method according to claim 26, wherein the first node includes a broadband switch, and the second node includes a narrowband switch; and wherein said step of

-58-

forwarding, by the second node, the communication to another node comprises the step of forwarding, by the second node, the communication to the another node using a narrowband transport mechanism; and wherein said step of receiving, at a first node, a communication comprises the step of receiving, at the first node, the communication on a broadband transport mechanism.

28. The method according to claim 25, wherein said step of sending, by the first node, the signaling information to a second node comprises the step of sending, by the first node, the signaling information to the second node over a first link, and wherein said step of sending, by the first node, the data information to the second node responsive to the at least one routing instruction comprises the step of sending, by the first node, the data information to the second node over a second link.

29. The method according to claim 25, wherein the first node includes a broadband switching fabric, and the second node includes a narrowband switching fabric and a switching intelligence.

30. The method according to claim 29, wherein the first node relies on the switching intelligence of the second node by responding to routing instructions.
