(57) **ABSTRACT**

Embodiments of the present invention assist in the development, management, and deployment of aggregated data attributes for multiple data sources. One embodiment provides a development interface that allows for elements of attributes, including filters, to be moved into a coding area in which an attribute or an attribute element is being edited. In another embodiment, the user interface presents data fields to assist in the development of filters for multiple data sources with divergent formats. The application further provides a validation interface through which users can validate attributes and trace the results returned by various elements referenced by the attributes under validation. Another embodiment provides a system for managing attributes and deploying them to various systems by creating a (Continued)

deployment file that is used by an attribute calculation system. In one embodiment, the attribute calculation system is a scalable system that dynamically calculates attributes for multiple data sources.

## SYSTEM AND METHOD FOR PROVIDING AN AGGREGATION TOOL

### CROSS-REFERENCE TO RELATED APPLICATIONS

This application is a continuation of U.S. patent application Ser. No. 15/464,089, filed Mar. 20, 2017, entitled "SYSTEM AND METHOD FOR PROVIDING AN AGGREGATION TOOL", which is a continuation of U.S. patent application Ser. No. 14/091,174 filed on Nov. 26, 2013, entitled "SYSTEM AND METHOD FOR PROVIDING AN AGGREGATION TOOL", which is a continuation of U.S. patent application Ser. No. 12/022,954 filed on Jan. 30, 2008, and which issued as U.S. Pat. No. 8,606,666, entitled "SYSTEM AND METHOD FOR PROVIDING AN AGGREGATION TOOL," which claims the benefit of priority under 35 U.S.C. § 119(e) of U.S. Provisional Patent Application No. 60/887,523 filed on Jan. 31, 2007, the entire contents of which are each hereby incorporated by reference in their entirety herein and should be considered a part of this application. All publications and patent applications mentioned in this specification are herein incorporated by reference in their entirety and made a part of this specification to the same extent as if each individual publication or patent application was specifically and individually indicated to be wholly incorporated by reference.

### BACKGROUND OF THE INVENTION

#### Field of the Invention

The disclosure relates generally to the field of scoring and prediction and to tools to improve the flexibility and efficiency in generating and evaluating aggregated attributes.

#### Description of the Related Art

There exists significant interest in information indicative of the relative financial risk or profitability of potential business transactions with individuals or other entities. For example, a lending institution is interested in the relative likelihood of a loan recipient timely and reliably making mutually agreed loan payments. An insurance company is interested in the relative likelihood of claims arising from an existing or potential client. Such predictive information is a factor in deciding whether to engage in a particular business transaction and/or the terms under which a transaction takes place.

A large variety of public records and privately developed databases can be utilized to inform such risk/benefit determinations. For example, credit reporting agencies (CRAs) collect and maintain information on a person's individual credit history. This information can include a total credit line on one or more accounts, current credit balance, credit ratios, satisfactorily paid accounts, any late payments or delinquencies, depth of credit history, total outstanding credit balance, and/or records of recent and/or historical inquiries into the person's credit. Governmental motor vehicle agencies generally maintain records of any vehicle code violations by a person as well as histories of reported accidents. Courts will generally maintain records of pending or disposed cases associated with a person, such as small claims filings, bankruptcy filings, and/or any criminal charges. Similar information also exists for large and small businesses, such as length of the business's existence,

reported income, profits, outstanding accounts receivable, payment history, market share, and so forth.

The extensive amount of data available for any given person or entity makes the task of evaluating a business decision regarding the person or entity very difficult. Accordingly, such raw data is frequently processed to facilitate more convenient and rapid financial decisions. For example, a person's raw financial data can be processed to produce a "score" indicative of their relative credit worthiness. Such a score can be utilized in decisions to extend the person or entity further credit and/or as a factor in determining an interest rate to be charged. The evaluation of the relative risk/benefit of a given decision is even more complex when considering multiple persons simultaneously, such as spouses, partnerships, sole proprietorships, joint ventures, LLCs or other entities. When considering multiple persons, raw data from multiple sources about each of the individuals may need to be evaluated.

Attributes can be used to calculate various types of scores and in many instances may be used on their own to guide business decisions as well. Attributes can be aggregated to target various aspects of credit histories, bankruptcy data, and other types of non-credit-based data. For example, a simple attribute could be "consumers who have opened a new credit line in the last 12 months." The results of the attribute would be a set of consumers who meets both the criteria of having opened a new credit line and having done so in the last 12 months. Therefore, attributes are important in facilitating the use of raw data for a variety of decisions that financial institutions and other entities may need to make.

### SUMMARY OF THE DISCLOSURE

Embodiments of the present invention provide systems and methods for creating, managing, and calculating attributes and filters for multiple data sources. One embodiment is an attribute toolbox (ATB) architecture that comprises an ATB user interface (ATB UI) and an ATB engine system.

One embodiment of the present invention is a system for creating and using credit data attributes, comprising an attribute repository for storing a plurality of credit data attributes, a first application server executing a platform-independent user interface application, a credit data repository, and a second application server executing an attribute calculation engine system, wherein the attribute calculation engine system is configured to retrieve credit data from the credit data repository and performs calculations on the credit data in accordance to the attributes in a deployment package generated by the user interface application. In one embodiment, the user interface application further comprises a development interface for editing credit data attributes, wherein the development interface is configured to retrieve the credit data attributes from the attribute repository for editing and return edited credit data attributes or newly created credit data attributes for saving in the attribute repository, a validation interface for testing credit data attributes, wherein the user interface application is configured to execute a validation engine to calculate credit data attributes on test credit data and display the results on the validation interface, and a management interface for managing the deployment of the credit data attributes, wherein the credit data attributes are saved into a deployment package.

Another embodiment is a system for creating of data attributes, comprising an attribute repository and a user interface application configured to receive a plurality of

requests from users. The attribute repository stores a plurality of data attribute elements, including attributes, filters, functions, operators, and data definitions. The user interface application further comprises a development interface for editing attribute elements, wherein the development interface is configured to retrieve attribute elements from the attribute repository for editing and return edited attribute elements or newly created attribute elements for saving in the attribute repository, and a validation interface for testing data attributes, wherein the user interface application is configured to execute a validation processing engine to calculate data attributes on test credit data and display the calculation results of the individual attribute elements on the validation interface.

One embodiment is a system for calculating credit data attributes, comprising at least one credit data repository, a first plurality of application servers executing a plurality of attribute calculation engines, a second plurality of application servers executing a plurality of data access engines, wherein the data access engines are configured to access data from the at least one credit data repository, and a third plurality of application servers executing a plurality of façade applications, wherein the façade applications are configured to receive a plurality of attribute calculation requests from a plurality of calling applications, send corresponding requests to the attribute calculation engines and data access engines, and return calculation results from the attribute calculation engines to the calling applications.

One embodiment is a method for building attributes for data from multiple data sources, comprising the steps of defining a plurality of filters, wherein each filter takes into account the format of a data source among a plurality of data sources, defining a plurality of data source-independent attributes, wherein the attributes operate on data selected by the plurality of filters, and creating a deployment package based on the plurality of attributes.

One embodiment is a method for calculating data scores based on data from multiple data sources, comprising the steps of selecting a plurality of data sets from a plurality of data sources, wherein each of the plurality of data sources stores its data in a different format, defining a plurality sets of filters, wherein each set of filters takes into account the format of each of the plurality of data sources, defining a plurality of data source-independent attributes, extracting a subset of data from each of the selected data sets in accordance to the filters, calculating the attributes based on the subset of data, and aggregating the results obtained from the step of calculating to create data scores.

One embodiment of the present invention is a system for creating and using data attributes, comprising an attribute repository for storing a plurality of data attributes, a first application server executing a platform-independent user interface application, a data repository, and a second application server executing an attribute calculation engine system, wherein the attribute calculation engine system is configured to retrieve data from the data repository and performs calculations on the data in accordance to the attributes in a deployment package generated by the user interface application. In one embodiment, the user interface application further comprises a development interface for editing data attributes, wherein the development interface is configured to retrieve the data attributes from the attribute repository for editing and return edited data attributes or newly created data attributes for saving in the attribute repository, a validation interface for testing data attributes, wherein the user interface application is configured to execute a validation engine to calculate data attributes on

test data and display the results on the validation interface, and a management interface for managing the deployment of the data attributes, wherein the data attributes are saved into a deployment package.

#### BRIEF DESCRIPTION OF THE DRAWINGS

Specific embodiments of the invention will now be described with reference to the following drawings, which are intended to illustrate embodiments of the invention, but not limit the invention:

FIG. 1 illustrates the architecture of the ATB architecture according to an embodiment;

FIG. 2 illustrates the hierarchy and the dependencies of systems, clients, attributes, filters, functions and raw data as used in one embodiment;

FIG. 3A illustrates an example deployment configuration of the ATB UI according to an embodiment;

FIG. 3B illustrates an example deployment configuration of the ATB engine system according to an embodiment;

FIG. 4A is a schematic diagram showing the implementation of the ATB UI according to one embodiment;

FIG. 4B is a schematic diagram showing the implementation of the ATB engine system according to one embodiment;

FIG. 5A is an example computer screen showing how attributes are located and managed in the ATB UI according to one embodiment;

FIG. 5B is an example computer screen showing the attribute development interface according to one embodiment;

FIG. 5C is an example computer screen showing how functions and operators can be added to attributes according to one embodiment;

FIG. 6A is an example computer screen showing the filter development interface according to one embodiment;

FIG. 6B is an example computer screen showing how details of a selected data source are displayed in the filter development interface according to one embodiment;

FIG. 6C is a computer screen showing a search and browse interface displaying how filters are used according to one embodiment;

FIG. 7 is an example computer screen of the validation interface showing the results of the validation engine according to one embodiment;

FIG. 8A is an example computer screen showing how a client system can be created in the ATB UI according to one embodiment;

FIG. 8B is an example computer screen showing how attributes can be associated with a client system for deployment according to one embodiment;

FIG. 8C is an example computer screen showing how multiple clients and systems are managed in the ATB UI according to one embodiment;

FIG. 9A is an example computer screen showing how multiple data sources are managed in the ATB UI according to one embodiment; and

FIG. 9B is an example computer screen showing how attributes and filters can be exported according to one embodiment.

#### DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

Embodiments of the ATB UI system architecture solve many problems associated with developing, managing, and deploying attributes. First, many common aggregated attri-

butes are often complex, referencing other attributes as well as filters that are data format dependent. The filters themselves have to be coded to access specific fields within a data source. For example, since each of the main CRAs in the United States maintains data in a different format, a separate filter is often used for each CRA. Therefore, the development of filters and attributes is often a tedious process and syntax errors frequently occur. Those skilled in the art will recognize that attributes can be developed for non-credit data sources, and the challenge of accounting for the individual formats of non-credit data sources exist as well. In one embodiment, the ATB UI includes a development interface that allows for filters and attributes to be moved via the UI, for example, into a coding area in which an attribute or a filter is being edited. In another embodiment, the ATB UI provides a filter development interface that presents data fields to the user. The interface simplifies the task of developing filters for multiple data sources that have different formats by presenting the data fields of the data sources in a graphical user interface. The fields can be moved into coding area as well, ensuring that proper data field references are included.

Second, the development of efficient and accurate attributes relies on extensive testing on raw data and constant revisions are made based on test results. Attributes often reference other attribute elements in a long chain of dependencies, including other attributes that may in turn reference numerous filters. For example, in developing an attribute that uses five other attributes, a developer may have to run numerous tests in order to arrive at the proper weight that should be accorded to each of the five attributes. In one embodiment, the ATB UI includes a validation interface that advantageously allows the user to see results returned by each attribute element that is referenced by the attribute that is currently being tested. One embodiment displays the results of each filter and each attribute that is referenced by the attribute that is being validated. This enables the user to quickly determining any errors or performance problems hidden in the chain of dependencies. The user can, for example, quickly determine that a filter is selecting a wrong field or that an attribute calculation is returning erroneous or undesirable results. The interface is particularly helpful in the development of aggregation attributes, which often reference a large number attributes and filters. The ability to trace the results of the individual elements is invaluable to the development of such attributes.

Third, institutions often require the use hundreds of attributes in multiple combinations to handle complex analysis and modeling on credit-based and non-credit based data. As a result, both the creation and maintenance of filters and attributes can require significant time and effort. Finally, the ability to effectively calculate attributes and scores on data from multiple data sources also presents significant challenges as well.

Embodiments of the ATB UI and ATB engine system architectures facilitate the management of the attributes and remove some of the difficulties that come with having to manually configure the deployment of attributes in system files. In one embodiment, the ATB UI allows users to associate groups of attributes into a system through a graphical user interface. The ATB UI also provides a comprehensive view of how attributes are deployed in various systems. Users can quickly and easily view the dependencies between attributes and the associated systems and determine how editing an attribute will affect the systems in their deployment scheme. In one embodiment, upon user request the ATB UI will automatically output a single

deployment package including all of the user's systems, along with the proper associations of attributes, filters, and other configuration information. The deployment package can then be used in the ATB engine system, a system that performs attribute calculations.

In one embodiment, the ATB engine system is configured to dynamically access multiple data sources and automatically performs attribute calculations based on the attributes included in the deployment package. In another embodiment, the ATB engine system can calculate the attributes on credit data for a related set of individuals or entities. In one embodiment, both the ATB UI and the ATB engine system are implemented in a component-based architecture with a high degree of flexibility, maintainability, and scalability. In one embodiment, multiple components can be hosted in a single environment. In another embodiment, the components can be distributed across a network with a load balancing server to manage and distribute requests among the components.

FIG. 1 depicts the architecture of an embodiment of the present invention. Attribute Toolbox (ATB) architecture 100 includes two main components: an ATB User Interface (ATB UI) module 102 and an ATB engine system 104. The ATB UI 102 presents a comprehensive user interface through which users can view, edit, validate, and simulate filters and attributes. The ATB engine system 104 takes the attributes created by the ATB UI 102, fetches data from the appropriate data sources, and performs calculations on the fetched data based on those attributes.

#### ATB UI

As shown in FIG. 1, the ATB UI 102 includes a presentation component 110, a business logic abstraction 112, an attribute/filter management business logic 114, and a data access layer 116.

#### Attribute Development

The presentation component 110 presents various user interfaces to assist in the development of filters and attributes and the management of their deployment to various systems. In one embodiment, the presentation component 110 further comprises filter and attribute development interfaces 150, a search/browse interface 152, a management interface 154, and a validation interface 156. The filter and attribute development interfaces 150 enable users to drag and drop existing data definitions, filters, functions, and attributes into a coding area and thereby substantially reducing the time and effort required to locate the proper elements that need to be added into new filters and attributes. The search interface 152 enables user to search for and browse filters, attributes, and clients/systems. The management interface 154 allows user to configure clients and systems and provides an interface through which attributes can be associated to systems for deployment. These user interfaces will be further described in conjunction with FIGS. 5A-9B. In one embodiment, the ATB UI 102 accepts requests from client computers 122 and responds by presenting the appropriate user interfaces to the client computers 122.

These user interfaces access objects and methods within the business logic abstraction 112 layer, which is an abstraction layer of the attribute/filter management business logic 114. Hence, any future changes in the implementation in the attribute/filter management business logic 114 will not necessarily necessitate recoding or reconfiguring the presentation component 110. The ATB UI 102 retrieves attributes and filters from the attribute/filter repository 118 through the data access layer 116. Likewise, new or edited filters and attributes are saved back to the repository 118. The attributes

can be standardized attributes such as standard aggregation (STAGG) attributes created by Experian, custom-made attributes, or both.

In one embodiment, the repository **118** implements a version control feature so that users of the ATB UI **102** can retrieve previous versions of attributes and filters. Furthermore, the ATB UI **102** provides a locking mechanism by which users can lock the attributes and filters that they are currently editing to prevent other users from changing them. The locking mechanism and the version control feature enable multiple users to collaborate on the development of attributes and filters.

In addition, one embodiment of the ATB UI **102** has user access control. For example, some users may be given rights to execute but not view attributes. Other users may have full rights to view and edit the attributes. In one embodiment, the user access rights are controlled by special serial numbers or passcodes, though it is recognized that a variety of security procedures and methods may be used. A user presents the proper serial number or passcode in order to view and edit attributes. The modularity of various interfaces, in addition to the user control feature of ATB UI **102**, allows users with various roles to collaborate on a project. For example, developers of attributes and filters may be granted full rights to view and modify attributes and filters, while business analysts may be granted limited rights to deploy the attributes to various systems. In another example, a company that specializes in developing attributes and filters may have full access rights while its customers who purchase the attributes and filters may be given limited rights to use but not view the attributes and filters.

#### Testing, Validation and Simulation

One main difficulty with attribute and filter development is the significant effort required for validation. Often attribute and filter developers have to test the attributes and filters on sample data and modify them repeatedly to improve performance and accuracy. In addition to this iterative process, developers have to account for the large number of dependencies that can potentially be in any attributes and filters. FIG. 2 illustrates the potential dependencies as used in one embodiment. Hierarchy **170** shows that clients are dependent on systems, which in turn are dependent on attributes. An example client may be a credit card company, and the company may have a number of systems for its credit card products. For example, one system may be used to screen commercial card applicants and another may be used to screen consumer card applicants. As such, the two systems have different attributes because the screening criteria for these two groups of applicants are different.

Retuning to the hierarchy, attributes are further dependent on filters, which in turn are dependent on the raw data definitions. This is because attributes are data-independent and filters are data dependent. In one embodiment, a filter must be defined for each data source. As shown in the hierarchy **170**, each filter can also reference other filters, functions and data definitions. Each attribute, in turn, can reference a number of filters, functions and other attributes. Thus, an error in a data definition in a single filter can adversely affect all filters that that reference that single filter, and in turn all attributes that reference those affected filters will be affected as well, and so on.

One embodiment of the ATB UI **102** addresses this difficulty by providing a validation engine **160** that allows for dependency tracing. In one example, an attribute A includes three other attributes B, C, D, and attributes B, C and D each additionally has three filters B1, B2, B3 and so

on. When the user decides to test attribute A on a test data set in the validation engine **160**, the validation interface **156** shows the user the results of applying filters B1, B2, B3, C1, C2, C3, D1, D2, and D3 to the sample data, as well as the results of calculating attributes B, C, and D. In addition, the validation interface **156** displays the raw data used in testing. Because each result in the chain of dependency for attribute A is displayed, the user can quickly locate any problem within the chain of dependency. For example, the user can see that attribute B is returning undesirable results, determine that filter B1 is incorrect, and adjust filter B1 to correct the problem. Because the dependencies can often be far more numerous and complex than this simple example, the validation interface **156** provides a powerful tracing tool for developers of attributes and filters for multiple data sources.

In addition to the validation engine **160**, embodiments also provide a simulation configuration wherein the user can utilize the ATB UI **102** to simulate the performance of their filters and attributes to see how they affect attribute and score calculations. In one embodiment, the ATB UI **102** provides an interface by which a user may connect a custom application so the user may simulate the attributes and filters created in the ATB UI **102** in the custom application.

#### ATB Viewer

Embodiments of the invention also include an ATB Viewer component. The ATB Viewer is a user interface that allows users to “view” parsed raw data, calculated filter or attribute results. Attributes and filters can be created and generated and the results can be stored. The results can further be returned to a custom/calling application selected by the user. If the user wishes to view the results immediately, he/she can access the ATB Viewer to have a general formatted overview of the results for a specific test case.

#### Management and Deployment

The ATB UI **102** allows users to manage the collections of filters and attributes that are slated for deployment in the ATB engine system **104**. Users can quickly create attributes and associate a group of attributes for deployment. For example, a bank user may create twenty attributes for its credit card operations and another fifty attributes for its home loan operations. The bank may then associate the twenty attributes to a “Credit Cards” system and the fifty attributes to a “Home Loans” systems by using the ATB UI **102**. The ATB UI **102** then outputs a deployment package **120** to be used by the ATB UI engine system **104**, which performs calculations based on these associated attributes included with the deployment package **120**. In one embodiment, the deployment package **120** is generated with the proper dependencies among the attributes and filters. Furthermore, the deployment package **120** can accommodate multiple systems, each with its own associated attributes. This one-step deployment function of this embodiment substantially eliminates the cost of having to code the dependencies of the attributes manually and enables rapid deployment of multiple systems with a single request sent to the ATB UI **102**.

#### ATB Engine System

The ATB engine system **104** retrieves and parses raw data, calculates attributes, and returns results. In the illustrated embodiment, the ATB engine system **104** comprises an ATB engine **106** and a data access engine **108**. In other embodiments, they can be combined into one engine. The ATB engine **106** calculates attributes or scores using data received from the data access engine **108**. In one embodiment, the ATB engine **106** comprises a parser **162**, which reads and parses data. In other embodiments, during calculation, the ATB engine **106** reads instructions in a manually created file

or a deployment file produced by the ATB UI **102**. The ATB engine **106** then instructs a business rules component **164**, which performs the actual calculations.

In one embodiment, the data access engine **108** accesses the external data source(s) **140** or reads the data from one or several files (for example, an automatic response format (ARF) file), parses the data, and sends it to the ATB engine **106** for calculation. The data access engine **108** comprises a mapper **166** and a communication module **168**. The mapper **166** handles the mapping of data fields in data sources **140** to objects within ATB engine system **104**. The communication module **168** handles the tasks of communicating with various data sources **140**. Because data access engine **108** accepts a wide variety of data input, it can be configured to access data from credit data sources **402** as well as data from non-credit data sources **404**, such as a local data source **406**. In one embodiment, the local data source **406** is a batch XML input. For example, a bank running an instance of the ATB engine **104** may configure the ATB engine **104** to perform attribute calculations on data from a credit bureau, a third-party data source, and/or its own internal customer data. In one embodiment, the results of the calculations are sent to a repository **148** so the calling application **124** may access them.

Because the ATB engine system **104** can handle multiple data sources, it can dynamically calculate the attributes across data sources as needed. Embodiments of the ATB engine system **104** can be configured to automatically calculate attributes across multiple data sources, whether in response to requests from a plurality of calling applications or a large volume of batch requests from batch files. The ability to handle calculations across multiple data sources in accordance to the incoming requests greatly assist in the evaluation of the relative risk/benefit of a given financial decision that involve multiple persons at the same time, such as spouses, partnerships, sole proprietorships, joint ventures, LLCs or other entities. Thus, unlike prior systems, users of the ATB engine system **104** will not have to access the data sources individually and perform attribute calculation for each source and then combine the results of their calculations. Similarly, the ATB engine system **104** will not have to perform an analysis on individuals separately and then combine the results.

#### Profile

Embodiments of the ATB engine system **104** additionally includes a profile component. In one embodiment the profile component is part of the façade **130**. A profile provides the ability to handle simple work flows. For example, one work flow may be a decision of call one data source versus another that depends on the results coming from a previous service request. For example, one profile can include instructions to the ATB engine system **104** to access an alternative data source in case a first request does not return the desired data. The profile workflow logic can include a variety of instructions and requests that can be executed based on the occurrence or non-occurrence of various conditions. Embodiments of ATB engine system include profiles that can handle roll-over logic, ZIP code tables and any other type of logic driven by one or several attribute calculations.

#### ATB UI Architecture

FIG. 3A depicts an embodiment of the ATB UI web server architecture. The illustrated ATB UI architecture **200** includes an ATB UI web server **202** configured to receive requests from a plurality of workstations or other remote computing devices **204**. In one embodiment, workstations or remote computing devices **204** send requests and receive responses via the HTTP or HTTPS protocols, and use web

browsers to solicit inputs and display the information to the end users. For example, an end user may be a bank that regularly extends credit to its customers. The bank may be able to use its computers to remotely interact with the ATB UI web server **202** in order to view, edit, validate, and test its own attributes and filters stored in relational databases **206**. In one embodiment, the ATB UI web server **202** is a self-contained Ruby on Rails application that acts as a web server. It communicates via the HTTP or HTTPS protocol in one embodiment. Syntax checking of attribute codes is accomplished through java-script on the client computers. It is recognized that other applications, protocols, and languages may be used.

#### ATB Engine Architecture

FIG. 3B illustrates an embodiment of the ATB engine system architecture. The illustrated ATB engine system architecture **220** includes a calling application **222**, a load balancer **224**, one or more façade web services **226**, data access engines **228**, ATB engines **230**, and a data storage **232**. In one embodiment, the calling application **222** is an application that sends calculation requests to the load balancer **224**. In other embodiments, the calling application **222** directly sends requests to the façade web service **226**. These requests include requests to calculate attributes and scores. For example, a bank may have a calling application that sends a request to calculate the number of customers who have the attribute of recently opening a credit line within the last twelve months. In one embodiment, the calling application is a custom-coded application. For example, a mortgage company may have a custom-coded application to process its loan applicants. In another embodiment, the calling application is a commercially available application such as Transact by Experian Decision Analytics. It is recognized that other applications may be used.

In one embodiment, the load balancer **224** receives requests from a plurality of calling applications **222** and distributes those requests to a plurality of the façade web services **226** in order to improve the efficiency of the overall architecture. Each façade web service **226** publishes objects and methods available for attribute calculation. Upon receipt of an incoming request from the calling application **224**, the façade web service **226** initiates the appropriate remote procedural calls (RPC) over the TCP/IP protocol to either the data access engine **228** or the ATB engine **230**. For example, the façade web service **226** may initiate a first RPC to the data access engine **228** to retrieve the requested data from the data storage **232** and then initiate a second RPC to the ATB engine **230** for calculation. The ATB engine **230** then calculates the results by applying attributes within the deployment package **120** to the retrieved data sets. In one embodiment, a user can use the ATB UI **102** to create the deployment package **120**. The final results are sent back to the calling application **222**. In the recently opened credit line example mentioned above, the results would be a list of customers who have opened a recent credit line.

The configuration depicted in FIGS. 3A and 3B is for illustrative purposes only and those skilled in the art will recognize that any number of components of the architecture can be used. In one embodiment, the architecture is designed to be scalable. For example, although not depicted, a plurality of calling applications and a plurality of credit bureau data sources can be used in the architecture. Moreover, the components can reside in a single computer environment or distributed across multiple computer environments.

FIG. 4A provides a more detailed depiction of the architecture of the ATB UI **102** according to one embodiment. As previously shown in FIG. 1, client computers **122** access the

ATB UI **102** over one or more communication networks. The presentation component **110** presents a user interface by which users can interact with the ATB UI **102**. Except for the web browsers located on client computers **122**, no installed code base of ATB UI needs to reside on client computers **122**. Communications from the browser interface to the presentation component **110** occur through URL navigation or HTTP requests.

The business logic abstraction layer **112** is an abstraction layer of the attribute/filter management business logic **114**. The abstraction layer **110** further comprises a filter manager **132**, an attribute manager **134**, and a client manager **136**. These managers present objects, systems and methods for viewing, editing, and managing filters, attributes, and systems to which the filters and attributes will employ. The managers have their corresponding counterparts within the business logic **114**, namely, a filter business component **142**, an attribute business component **144**, and a client business component **146**. The three business components work with a repository object **120** within the data access layer **116** for transactions involving the repository **118**. In this example embodiment, the repository **118** comprises a SQLite database server, but those skilled in the art will recognized that other database servers such as Oracle, mySQL, Microsoft SQL Server, and IBM DB2 can be used as well.

The abstraction layer **112** serves as a liaison between the presentation component **110** and the business logic **114**. The abstraction layer **112** also provides security enforcement functions in one embodiment. For example, it ensures that attributes are only displayed for the users who have the proper access rights to view them. In one embodiment, the abstraction layer **112**, the business logic **114** and the data access layer **116** are implemented in a Ruby on Rails environment, which has the advantages of providing ease of maintenance and a modular programming construct, though other environments may be used.

As shown in FIG. 4A, the ATB UI **102** further includes a core services component **254** and a support service component **256**. In one embodiment, the core services component **254** is a Rails framework comprising a security component **260**, an exception component **262**, an export/import component **264**, and a logger component **266**. The security component **260** provides the logic for security enforcement, which limits access to the attributes and filters to those users who have the proper levels of access rights. The exception component **262** handles exceptions generated by any component within the ATB UI **102**. The export/import component **264** is a data interchange service that supports and provides the capability to export and import ATB entities (for example, attributes) from and into the ATB UI **102**. The logger component **266** is served by the Ruby log 4r library in one embodiment. It provides the functionality to publish messages to external log stores and to control the type and volume of data logged. The support service component **256** comprises a reporting component **268**, which provides a set of pre-defined reports that can be run. In one embodiment, the generated reports are templates for specification documents and include attributes and related results.

FIG. 4B is a schematic diagram showing the implementation of the ATB engine system **104** according to one embodiment. The façade **130** includes two methods of accepting requests. It has a web service component **270** and a batch component **272**. In one embodiment, the web service component **270** is supported by a SOAP4R component **294** within technical services **288**. SOAP4R is a Simple Object Access Protocol (SOAP) implementation in the Ruby programming language. The web service component **270** thus

accepts SOAP requests from calling applications. Alternatively, the batch component **272** reads batched requests in a repository **298**. In one embodiment, the repository **298** is a hard drive.

In either case, once an incoming request has been received, the façade **130** begins the process of managing the request and performs the necessary work in order to return a response to the request. First, the façade **130** has a message publisher **276** that will publish a message to either the ATB engine **106** or the data access engine **108**. In one embodiment, the message is a RPC sent via the TCP/IP protocol. The façade **130** includes managing logic that will handle the sequence in which RPCs are sent. The façade **130** additionally includes a profile component that handles a variety of work-flow logic as described earlier.

Both the ATB engine **106** and the data access engine **108** have a message subscriber component that subscribes to the message publisher **276**. In the ATB engine **106**, once the message subscriber **278** receives a message from the message publisher **276**, it will instruct business component **280** to perform calculations. In one embodiment, business component **280** further comprises the parser **162** and the business rules component **164**. The business rules component **164** performs calculations based on the attributes and filters within deployment package **120**, using data parsed by the parser **162**. In one embodiment, the business component **280** is implemented in the Lua scripting language, which provides fast execution times and increased performance. This is particularly important in some embodiments because the ATB engine system may be configured to receive a high volume of requests from the batch component **272** and to accept a large number of requests from calling applications through the web service **270**. The façade **130** and the access engine **108** are implemented in the Ruby programming language in one embodiment.

Access engine **108** also includes the aforementioned message subscriber **282** and a data source access framework **284**. After the message subscriber **282** receives a message from the message publisher **276**, it will instruct the data source access framework **284** to access the requested data. The data source access framework reads a data source definition file **286** in order to determine the data formats of the various data sources that are being accessed. Finally, technical services **288** include a log 4r component that provides logging capability for debugging purposes.

#### Attribute Interfaces

FIG. 5A is an example computer screen showing the attribute search/browse interface **152** in the ATB UI **102** according to one embodiment. As shown, a search panel **302** is provided so users can search for attributes by various parameters such as name/keyword, system, and format. In response, the ATB UI **102** displays a sortable list **304** of attributes stored in the repository **118** that match the search parameters. For each attribute, the ATB UI **102** shows the system in which the attribute is being deployed, as well as whether the attribute is locked by another user who is viewing or editing it.

The ATB UI **102** facilitates the management of the attributes and removes some of the difficulties of having to manually configure the deployment of attributes. Because the UI provides a comprehensive view of how attributes are deployed in various systems, users can quickly and easily view the dependencies between attributes and the associated systems and determine how editing an attribute will affect the systems in their deployment scheme. In addition, because the name of each attribute listed is a link to the attribute development interface with that selected attribute

shown in a coding area, the users can quickly launch into the development environment from the list **304**.

FIG. **5B** is an example computer screen showing how attributes can be edited in the attribute development interface **150** according to one embodiment. As shown, an example attribute is being edited or created in a coding area **314**. Because attributes often reference numerous other attributes, filters, functions, and operators, the development interface **150** provides a panel **312** that lists other attributes, filters, functions, and operators that can be inserted into the coding area **314**. This ensures that the newly created attribute or the edited attribute will have the proper dependencies. In one embodiment, the list is populated by the attributes and filters retrieved from the repository **118**. Any attribute or filter listed can be moved (for example, dragged and dropped) into the coding area **314**, and a proper reference to that attribute or filter automatically appears within the coding area **314**.

In addition, the panel **312** has a tab area **316**, which has two other tabs “filters” and “functions & operators” as shown. A user can select one of the other tabs and brings up either the filters or the functions and operators that are available. Likewise, these elements can be dragged and dropped into the coding area **314** and the proper references are automatically created. FIG. **5C** shows an example of the panel **312** after a user selects the “functions & operators” tab within the tab area **316**. Any of the functions and operators shown can be moved (for example, dragged and dropped) into the coding area **314**. Therefore, the development interface **150** enables users to rapidly code new attributes or modify existing attributes with accurate references to other attributes, filters, functions, and operators.

#### Filter Interfaces

FIG. **6A** is one embodiment of an example computer screen of the filter development interface **150**. Similar to the attribute development interface shown in FIG. **5B**, the filter development interface presents other filters, functions, and operators in a panel **322** that can be dragged and dropped into a coding area **324**.

#### Coding Filters for Various Data Sources

Because of the complexities of database definitions, the task of developing filters on raw data is often left to programmers. To overcome this problem, the filter development interface **150** simplifies the task of developing filters for various data sources by showing the data fields within segments of the data sources. Therefore, in addition to filters, functions, and operators, the filter development interface has a “raw data” tab in the tab area **326**. As shown in FIG. **6A**, the available data segments in the data source “Experian” are listed in the panel **322**. The fields within the segments are available to be dragged and dropped into the coding area **324**. As shown, the coding area **324** shows the codes the filter that is being developed.

FIG. **6B** is an example computer screen showing how filters can be developed for different data sources in the ATB UI. As shown in FIG. **6B**, data fields for a selected segment within a selected data source are listed in the panel **322**. Drop down boxes **320** include a data source drop-down box, a segment drop-down box, and an argument drop-down box. The data source is selected at the data source drop-down box, and the data segment is selected at the segment drop-down box and so on. In this example, the “Experian” data source has been selected and a segment has also been selected. In one embodiment, all available valid segments associated with the selected data source are listed in the segment drop-down box.

In one embodiment, once a segment is selected, all the available data fields are shown within the panel **322**. The user can drag and drop a field into the coding area **324**. Through the filter development interface **150**, a user can easily scan through the available fields within the segments in a data source and quickly and accurately add the necessary fields to a filter that is currently being edited in the coding area **324**. This interface minimizes errors and speeds up the development of filters for multiple data sources with different data formats.

FIG. **6C** is a computer screen showing the filter search/browse interface **152**. Much like the interface shown FIG. **5A** for attributes, users can search for filters and the search results will be displayed in a listing **340**. Each filter is listed with status information, whether it has been locked by another user for editing, and whether it has been encoded for a particular data source (as indicated by the check marks). Clicking on the name of the filter will launch a development interface similar to the one shown in FIG. **6A**, where the user can edit the selected filter.

#### Syntax Checking and Validation

In one embodiment, ATB UI provides a syntax checking engine that checks the syntax of a filter or an attribute within a current coding area if requested by the user. As shown in FIG. **6A**, once the user selects a “Check Syntax” button **330**, the ATB UI will run a syntax check on either the filter or attribute that is currently being edited. For example, FIG. **6A** shows the syntax check window **328** displaying a message indicating that the syntax check engine has discovered a syntax error on line **13** of the example filter. The syntax check engine can likewise check for syntax errors within an attribute. Thus users of the ATB UI can avoid saving invalid filters or attributes. In other embodiments, a syntax check is automatically performed when a user attempts to save a filter or an attribute to the repository **118**, or save changes to an existing filter or attribute.

Besides a syntax checking engine, embodiments of ATB UI also provide the validation interface **156** and the validation engine **160** (shown in FIG. **1**) through which users can validate attributes against test data. FIG. **7** shows an example computer screen of the validation interface **156**. The validation interface **156** includes an information/selection area **350**, which further includes a data file selector **352** and a data source selector **354**. Using the data file selector **354**, the user can select a sample test file including test data for the data source that the user selects in the data source selector **354**. In the example shown, the user has selected a file including sample data from the data source “Experian” to be sent to the validation engine **160**. In one embodiment, the validation engine **160** accepts test files for in the ARF format.

In the example shown in FIG. **7**, the validation engine **160**, through the validation interface **156**, provides a result **358** for the selected attribute “ALL002.” The validation engine **160** has calculated the attribute “ALL002” against the test data and has determined that the result is 52.0. More importantly, the validation interface **156** further includes a validation table **356** in which a user can examine the raw data and the dependencies within the attribute that is undergoing validation. The column headings of the validation table **356** show all the depending filters and attributes referenced in the code of attribute “ALL002.” The rows of the validation table **356** show raw data from the test file.

The validation interface **156** advantageously allows the user to see exact results returned by each filter or attribute referenced by the attribute that is being validated. This enables the user to quickly determining any errors or per-

formance problems hidden in the chain of dependencies. The user can, for example, quickly determine that a filter is selecting a wrong field or that an attribute calculation is returning erroneous or undesirable results. The validation interface 156 is particularly helpful in the development of aggregation attributes, which often reference a large number of attributes and filters.

#### System Management

FIG. 8A is one embodiment of an example computer screen showing how a client can be created in the ATB UI. An input interface 360 solicits configuration information that is needed to create a new client. The input interface 360 includes a listing of data sources that the new client will access, as well as a listing of systems that will be associated with this new client. When the user attempts to save the client configuration information, the ATB UI will check for errors and display an error message 362 (as shown) if needed.

FIG. 8B is one embodiment of an example computer screen showing how attributes can be associated with a client system for deployment. As an example, a client who is a bank may wish to deploy various systems associated with its needs. The bank may thus have one system that screens potential home loan applicants and another system for finding prospective commercial credit card applicants. Because each system requires different data and calculations, the bank client may wish to configure each one differently. The ATB UI provides an interface 366 to allow a client user to associate various attributes to a system for deployment. The interface 366 includes an available attribute listing 368 and a deployment attribute listing 370. The user can search for and browse attributes that are available for deployment in the listing 368 and then add the attributes to the deployment listing 370 by using an arrow selector 372. The attributes will then be slated for deployment for the particular system.

FIG. 8C is one embodiment of an example computer screen showing how multiple client system deployments are managed in the ATB UI. A system listing 380 lists systems that are available for deployment. Each system is listed with a name, a historical data entry including the date of last deployment, status, and the number of associated attributes. Under the status column, the ATB UI may indicate whether a system is ready or not ready for deployment. Some systems may not be ready to be deployed because they may have attributes with syntax errors or no attributes at all. The system listing 380 provides a way for the user to browse through the available systems and quickly determine which are ready for deployment. Furthermore, the ATB UI provides a link to the attributes so the user can quickly view or edit the attributes associated with the systems. The user is also given the option to select multiple systems from the listing 380 and deploy all of them at the same time. The deployment package 120 is then automatically created and can be used in ATB engine system 104.

#### Managing Data Sources and Attribute Exports

FIG. 9A is one embodiment of an example computer screen showing how multiple data sources are managed in the ATB UI 102. The ATB UI 102 provides a data source listing 386 that lists the available data sources. Each entry lists the short and long names of the data source as well as the time when the data source was last modified. The ATB UI 102 also provides a data source area 388 that displays the detail information of a data source that has been selected. The user can then view or edit the details of a particular data source, including the location of the file from which data can be obtained.

FIG. 9B is one embodiment of an example computer screen showing how attributes can be exported to a file. A system listing 390 provides a listing of systems that can be exported. Once exported, the file will include all attributes associated with the selected system. The export function allows multiple users from various sites to collaborate on a project. In one embodiment, users at remote sites without access to the centralized repository can run their own copies of the ATB UI 102. For example, a first user may be developing attributes and filters on a laptop while traveling. The export function enables the first user to export the attributes and filters and send the export file to a second user who runs a different instance of the ATB UI 102 that has a connection to a centralized repository. The second user will then be able to import the attributes created by the first user and save the attributes to the centralized repository. In one embodiment, the ATB UI 102 checks the import file against the repository, so that duplicate attributes are shown to the user. The second user will then have the option of overwriting the attributes that are in the repository with the imported version. In this manner, numerous users from various remote locations, even those without connection to a centralized attribute repository, can independently develop attributes and filters and merge their work later.

#### Various Embodiments of System and Method Implementations

In one embodiment, the systems and methods for generating and calculating attributes may be embodied in part or in whole in software that is running on one or more computing devices. The functionality provided for in the components and modules of the computing device(s) may comprise one or more components and/or modules. For example, the computing device(s) may comprise multiple central processing units (CPUs) and one or more mass storage device(s), such as may be implemented in an array of servers.

In general, the word “module,” “application”, or “engine,” as used herein, refers to logic embodied in hardware and/or firmware, and/or to a collection of software instructions, possibly having entry and exit points, written in a programming language, such as, for example, Java, Ruby, Ruby on Rails, Lua, C and/or C++. These may be compiled and linked into an executable program, installed in a dynamic link library, or may be written in an interpreted programming language such as, for example, BASIC, Perl, or Python. It will be appreciated that modules, applications, and engines may be callable from others and/or from themselves, and/or may be invoked in response to detected events or interrupts. Instructions may be embedded in firmware, such as an EPROM.

It will be further appreciated that hardware may be comprised of connected logic units, such as gates and flip-flops, and/or may be comprised of programmable units, such as programmable gate arrays or processors. The modules, applications, and engines described herein are in certain applications preferably implemented as software modules, but may be represented in hardware or firmware in other implementations. Generally, the modules, applications, and engines described herein refer to logical modules that may be combined with other modules and/or divided into sub-modules despite their physical organization or storage.

In some embodiments, the computing device(s) communicates with one or more databases that store information, including credit data and/or non-credit data. This database or databases may be implemented using a relational database, such as SQLite, Sybase, Oracle, CodeBase, mySQL, and

Microsoft® SQL Server as well as other types of databases such as, for example, a flat file database, an entity-relationship database, and object-oriented database, and/or a record-based database.

In one embodiment, the computing device is IBM, Macintosh, and/or Linux/Unix compatible. In another embodiment, the computing device comprises a server, a laptop computer, a cell phone, a Blackberry, a personal digital assistant, a kiosk, or an audio player, for example. In one embodiment, the computing device includes one or more CPUs, which may each include microprocessors. The computing device may further include one or more memory devices, such as random access memory (RAM) for temporary storage of information and read only memory (ROM) for permanent storage of information, and one or more mass storage devices, such as hard drives, diskettes, or optical media storage devices. In one embodiment, the modules of the computing are in communication via a standards based bus system, such as bus systems using Peripheral Component Interconnect (PCI), Microchannel, SCSI, Industrial Standard Architecture (ISA) and Extended ISA (EISA) architectures, for example. In certain embodiments, components of the computing device communicate via a network, such as a local area network that may be secured.

The computing is generally controlled and coordinated by operating system software, such as the Windows 95, Windows 98, Windows NT, Windows 2000, Windows XP, Windows Vista, Linux, SunOS, Solaris, PalmOS, Blackberry OS, or other compatible operating systems. In Macintosh systems, the operating system may be any available operating system, such as MAC OS X. In other embodiments, the computing device may be controlled by a proprietary operating system. Conventional operating systems control and schedule computer processes for execution, perform memory management, provide file system, networking, and I/O services, and provide a user interface, such as a graphical user interface (GUI), among other things.

The computing device may include one or more commonly available input/output (I/O) devices and interfaces, such as a keyboard, mouse, touchpad, microphone, and printer. Thus, in one embodiment the computing device may be controlled using the keyboard and mouse input devices, while in another embodiment the user may provide voice commands to the computing device via a microphone. In one embodiment, the I/O devices and interfaces include one or more display device, such as a monitor, that allows the visual presentation of data to a user. More particularly, a display device provides for the presentation of GUIs, application software data, and multimedia presentations, for example. The computing device may also include one or more multimedia devices, such as speakers, video cards, graphics accelerators, and microphones, for example.

In one embodiment, the I/O devices and interfaces provide a communication interface to various external devices. For example, the computing device may be configured to communicate with one or more networks, such as any combination of one or more LANs, WANs, or the Internet, for example, via a wired, wireless, or combination of wired and wireless, communication links. The network communicates with various computing devices and/or other electronic devices via wired or wireless communication links.

Although the foregoing invention has been described in terms of certain embodiments, other embodiments will be apparent to those of ordinary skill in the art from the disclosure herein. Moreover, the described embodiments have been presented by way of example only, and are not intended to limit the scope of the inventions. Indeed, the

novel methods and systems described herein may be embodied in a variety of other forms without departing from the spirit thereof. Accordingly, other combinations, omissions, substitutions and modifications will be apparent to the skilled artisan in view of the disclosure herein. For purposes of discussing the invention, certain aspects, advantages and novel features of the invention have been described herein. Of course, it is to be understood that not necessarily all such aspects, advantages or features will be embodied in any particular embodiment of the invention.

What is claimed is:

1. A computer-implemented method for generating attributes, the computer-implemented method comprising:
  - receiving, via a validation user interface that includes options that enable a user to define and deploy filters and attributes associated with different data sources having different data formats, a user selection of an attribute, wherein the attribute relates to a type of credit data;
  - identifying a credit data attribute formula expression based on the received user selection of the attribute;
  - displaying, via the validation user interface, dependencies between the attribute and a plurality of filters, wherein a first filter of the plurality of filters is configured to extract data from a first data source having a first data format by mapping one or more data fields in the first data source to the type of credit data and a second filter of the plurality of filters is configured to extract data from a second data source having a second data format by mapping one or more data fields in the second data source to the type of credit data;
  - generating a deployment package by compiling the credit data attribute formula expression into computer executable code; and
  - deploying the deployment package to a computing system, wherein the deployment package includes one or more computer instructions that when executed, generates an attribute value by at least:
    - extracting a subset of data associated with the attribute from the first data source in accordance with the first filter; and
    - applying the subset of data associated with the attribute from the first data source to the credit data attribute formula expression.
2. The computer-implemented method of claim 1 further comprising:
  - accessing a dependency tracing indicative of a dependency between the attribute, and an operator; and
  - displaying a result of applying the data associated with the attribute to at least a portion of the computer executable code of the credit data attribute formula expression.
3. The computer-implemented method of claim 1, further comprising:
  - receiving, from the validation user interface, user information associated with a user;
  - generating a user profile;
  - adding the received user information to data fields of the user profile; and
  - storing the identified credit data attribute formula expression in the user profile.
4. The computer-implemented method of claim 3, further comprising:
  - receiving, from the validation user interface, user information associated with a client of the user;
  - adding the received user information to data fields of the user profile; and

19

associating the identified credit data attribute formula expression with the received user information in the user profile.

5. The computer-implemented method of claim 1, further comprising retrieving, from the validation user interface, a user selection of a version command to store the credit data attribute formula expression as one version of a plurality of versions of the credit data attribute formula expression.

6. The computer-implemented method of claim 1, further comprising retrieving, from the validation user interface, a user selection of other user access authorization, wherein the user selection includes at least authorization to use the credit data attribute formula expression without authorization to edit the credit data attribute formula expression.

7. The computer-implemented method of claim 1, further comprising determining at least one weighting to be applied to the attribute.

8. The computer-implemented method of claim 1, further comprising causing display of dependencies between the attribute, and an operator.

9. A system for generating attributes, the system comprising:

one or more processors; and

non-transitory computer storage comprising code executable by the one or more processors, the executable code causing the one or more processors to perform operations including:

receiving, via a validation user interface that includes options that enable a user to define and deploy filters and attributes associated with different data sources having different data formats, a user selection of an attribute, wherein the attribute relates to a type of credit data;

identifying a credit data attribute formula expression based on the received user selection of the attribute;

displaying, via the validation user interface, dependencies between the attribute and a plurality of filters, wherein a first filter of the plurality of filters is configured to extract data from a first data source having a first data format by mapping one or more data fields in the first data source to the type of credit data and a second filter of the plurality of filters is configured to extract data from a second data source having a second data format by mapping one or more data fields in the second data source to the type of credit data;

generating a deployment package by compiling the credit data attribute formula expression into computer executable code; and

deploying the deployment package to a computing system, wherein the deployment package includes one or more computer instructions that when executed, generates an attribute value by at least:

extracting a subset of data associated with the attribute from the first data source in accordance with the first filter; and

applying the subset of data associated with the attribute from the first data source to the credit data attribute formula expression.

10. The system of claim 9 wherein the operations further include:

accessing a dependency tracing indicative of a dependency between the attribute, and at least one function or operator; and

displaying a result of applying the data associated with the attribute to at least a portion of the credit data attribute formula expression.

20

11. The system of claim 9 wherein the operations further include:

receiving, from the validation user interface, user information associated with a user;

generating a user profile;

adding the received user information to data fields of the user profile; and

storing the identified credit data attribute formula expression in the user profile.

12. The system of claim 11, wherein operations further include:

receiving, from the validation user interface, client information associated with a client of the user;

adding the received user information to data fields of the user profile; and

associating the identified credit data attribute formula expression to the received user information in the user profile.

13. The system of claim 9, wherein the operations further include retrieving, from the validation user interface, a user selection of a version command to store the credit data attribute formula expression as one version of the credit data attribute formula expression.

14. The system of claim 9, wherein the operations further include retrieving, from the validation user interface, a user selection of a lock command to lock the identified credit data attribute formula expression.

15. A non-transitory computer storage medium which stores a client application comprising executable code, the executable code causing a computing device to perform operations that comprise at least:

receiving, via a validation user interface that includes options that enable a user to define and deploy filters and attributes associated with different data sources having different data formats, a user selection of an attribute, wherein the attribute relates to a type of credit data;

identifying a credit data attribute formula expression based on the received user selection of the attribute;

displaying, via the validation user interface, dependencies between the attribute and a plurality of filters, wherein a first filter of the plurality of filters is configured to extract data from a first data source having a first data format by mapping one or more data fields in the first data source to the type of credit data and a second filter of the plurality of filters is configured to extract data from a second data source having a second data format by mapping one or more data fields in the second data source to the type of credit data;

generating a deployment package by compiling the credit data attribute formula expression into computer executable code; and

deploying the deployment package to a computing system, wherein the deployment package includes one or more computer instructions that when executed, generates an attribute value by at least:

extracting a subset of data associated with the attribute from the first data source in accordance with the first filter; and

applying the subset of data associated with the attribute from the first data source to the credit data attribute formula expression.

16. The non-transitory computer storage medium of claim 15, wherein the operations further comprise:

accessing a dependency tracing indicative of a dependency between the attribute, and at least one function or operator; and

displaying a result of applying the data associated with the attribute to the at least one function or operator.

17. The non-transitory computer storage medium of claim 15, wherein the operations further comprise:

- receiving, from the validation user interface, user information associated with a user;
- generating a user profile;
- adding the received user information to data fields of the user profile;
- storing the attribute, and at least one function or operator in the user profile;
- receiving, from the validation user interface, client information associated with a client of the user;
- adding the received client information to data fields of the user profile; and
- associating the attribute, and the at least one function or operator with the received client information in the user profile.

18. The non-transitory computer storage medium of claim 15, wherein generating the attribute value for the attribute includes generating the attribute value using a simulation file, and wherein the first data source is a simulated data source.

19. The non-transitory computer storage medium of claim 15, wherein the executable code is configured to be executed in response to a calling function.
