(57) ABSTRACT

Aspects of a method and system for an RF front-end calibra tion scheme using signals from a fractional-N frequency syn thesized and received signal strength indicator (RSSI) are provided. A frequency synthesizer within a wireless receiver may generate a signal for dynamically modifying again in an integrated low-noise amplifier (LNA) for each selected receiver channel. The frequency-synthesized signals may be applied to at least one tunable load communicatively coupled to the LNA. The tunable load may be an input load or an output load. The signal generated by the frequency synthe sizer may be sequentially applied to the input load and the output load. A logarithmic amplifier may generate an RSSI signal from the LNA output during the calibration process. The RSSI signal may be utilized for controlling a tunable load coupled to the LNA and optimize the tuning of the LNA in a desired channel by adjusting the tunable load.

METHOD AND SYSTEM FOR RF FRONT-END CALIBRATION SCHEME USING FRACTIONAL-N FREQUENCY SYNTHESIZED SIGNALS AND RSS

CROSS-REFERENCE TO RELATED APPLICATIONS/INCORPORATION BY REFERENCE

[0001] This application makes reference to, claims priority to, and claims the benefit of U.S. Provisional Application Ser. No. 60/778,232 filed on Mar. 2, 2006.

[0002] This patent application makes reference to:

U.S. application Ser. No. 1 1/385,390 filed on Mar. 21, 2006: U.S. application Ser. No. 1 1/385.423 filed on Mar. 21, 2006: and

U.S. application Ser. No. _______ (Attorney Docket No. 17539US01) filed on even date herewith.

[0003] The above stated applications are hereby incorporated by reference in their entirety.

FIELD OF THE INVENTION

[0004] Certain embodiments of the invention relate to onchip RF tuners. More specifically, certain embodiments of the invention relate to a method and system for an RF front-end calibration scheme using signals from a fractional-N fre quency synthesizer and a received signal strength indicator (RSSI).

BACKGROUND OF THE INVENTION

[0005] Broadcasting and telecommunications have historically occupied separate fields. In the past, broadcasting was largely an "over-the-air" medium while wired media carried telecommunications. That distinction may no longer apply as both broadcasting and telecommunications may be delivered over either wired or wireless media. Present development may adapt broadcasting to mobility services. One limitation has been that broadcasting may often require high bitrate data transmission at rates higher than could be supported by existing mobile communications networks. However, with emerging developments in wireless communications technology, even this obstacle may be overcome.

0006 Terrestrial television and radio broadcast networks have made use of high power transmitters covering broad service areas, which enable one-way distribution of content to user equipment such as televisions and radios. By contrast, wireless telecommunications networks have made use of low power transmitters, which have covered relatively small areas known as "cells'. Unlike broadcast networks, wireless net works may be adapted to provide two-way interactive ser vices between users of user equipment such as telephones and computer equipment.

[0007] The introduction of cellular communications systems in the late 1970's and early 1980's represented a significant advance in mobile communications. The networks of this period may be commonly known as first generation, or "1G" systems. These systems were based upon analog, circuit switching technology, the most prominent of these systems may have been the advanced mobile phone system (AMPS). Second generation, or "2G" systems ushered improvements in performance over 1G systems and introduced digital tech nology to mobile communications. Exemplary 2C systems include the global system for mobile communications (GSM), digital AMPS (D-AMPS), and code division multiple access (CDMA). Many of these systems have been designed according to the paradigm of the traditional telephony archi tecture, often focused on circuit-switched services, voice traf fic, and supported data transfer rates up to 14.4 kbits/s. Higher data rates were achieved through the deployment of "2.5G" networks, many of which were adapted to existing 2G net work infrastructures. The 2.5G networks began the introduc tion of packet-switching technology in wireless networks. However, it is the evolution of third generation, or "3G" technology that may introduce fully packet-switched net works, which support high-speed data communications.

[0008] Standards for digital television terrestrial broadcasting (DTTB) have evolved around the world with different systems being adopted in different regions. The three leading DTTB systems are, the advanced standards technical com mittee (ATSC) system, the digital video broadcast terrestrial (DVB-T) system, and the integrated service digital broadcast ing terrestrial (ISDB-T) system. The ATSC system has largely been adopted in North America, South America, Tai wan, and South Korea. This system adapts trellis coding and 8-level vestigial sideband (8-VSB) modulation. The DVB-T system has largely been adopted in Europe, the Middle East, Australia, as well as parts of Africa and parts of Asia. The DVB-T system adapts coded orthogonal frequency division multiplexing (COFDM). The OFDM spread spectrum technique may be utilized to distribute information over many carriers that are spaced apart at specified frequencies. The OFDM technique may also be referred to as multi-carrier or discrete multi-tone modulation. This technique may result in spectral efficiency and lower multi-path distortion, for example. The ISDB-T system has been adopted in Japan and adapts bandwidth segmented transmission orthogonal fre quency division multiplexing (BST-OFDM). The various DTTB systems may differ in important aspects; some sys tems employ a 6 MHZ channel separation, while others may employ 7 MHz or 8 MHZ channel separations.

[0009] While 3G systems are evolving to provide integrated Voice, multimedia, and data services to mobile user equipment, there may be compelling reasons for adapting DTTB systems for this purpose. One of the more notable reasons may be the high data rates that may be Supported in DTTB systems. For example, DVB-T may support data rates of 15 Mbits/s in an 8 MHz channel in a wide area single frequency network (SFN). There are also significant challenges in deploying broadcast services to mobile user equip ment. Because of form factor constraints, many handheld portable devices, for example, may require that PCB area be minimized and that services consume minimum power to extend battery life to a level that may be acceptable to users. Another consideration is the Doppler effect in moving user equipment, which may cause inter-symbol interference in received signals. Among the three major DTTB systems, ISDB-T was originally designed to support broadcast ser vices to mobile user equipment. While DVB-T may not have been originally designed to support mobility broadcast services, a number of adaptations have been made to provide support for mobile broadcast capability. The adaptation of DVB-T to mobile broadcasting is commonly known as DVB handheld (DVB-H). The broadcasting frequencies for Europe are in UHF (bands IV/V) and in the US, the 1670-1675 MHz band that has been allocated for DVB-H operation. Addi tional spectrum is expected to be allocated in the L-band world-wide. Broadcasting frequencies for VHF channels may range between 174-240 MHZ, for example.

[0010] To meet requirements for mobile broadcasting the DVB-H specification supports time slicing to reduce power consumption at the user equipment, addition of a 4K mode to enable network operators to make tradeoffs between the advantages of the 2K mode and those of the 8K mode, and an additional level of forward error correction on multi-protocol encapsulated data-forward error correction (MPE-FEC) to presented by mobile reception of signals and to potential limitations in antenna designs for handheld user equipment. DVB-H may also use the DVB-T modulation schemes, like QPSK and 16-quadrature amplitude modulation (16-QAM).

0011 While several adaptations have been made to pro vide support for mobile broadcast capabilities in DVB-T, concerns regarding device size, cost, and/or power require ments still remain significant constraints for the implementa tion of handheld portable devices enabled for digital video broadcasting operations. For example, typical DVB-T tuners or receivers in mobile terminals may employ super-heterodyne architectures with one or two intermediate frequency (IF) stages and direct sampling of the passband signal for digital quadrature down-conversion. Moreover, external tracking and SAW filters may generally be utilized for chan nel selection and image rejection. Such approaches may result in increased power consumption and high external component count, which may limit their application in hand held portable devices. As a result, the success of mobile broadcast capability of DVB-T may depend in part on the ability to develop TV tuners that have smaller form factor, are produced at lower cost, and consume less power during operation.

[0012] In the presence of large blocker signals, the gain of the low noise amplifiers (LNAs), and other components of the receiver have to be very linear, that is, the output has to have a linear relationship with the input, to maintain the perfor mance of the receiver. This causes increased power consump tion by the receiver due to the highly linear characteristics of various components in the receiver. Blocker signals are unwanted signals in frequency channels outside the wanted channel that disturb the reception of the wanted signals. This happens due to the fact that the blockers generate large signals within the receiver path. These large signals may introduce harmonics and intermodulation products or unwanted mixing products that causes crosstalk with the wanted signals. Simi larly, when the required RF signal is weak, there is an increase in the power consumption of the receiver to achieve a good noise factor (NF) and a good phase noise. In handheld com munication devices such as cell phones, and smart phones, the increased power consumption may significantly drain the battery that powers these devices.

[0013] Moreover, the gain in the LNA may be different for the wanted channel and for the blocker or interference signal. An LNA is usually "tuned" for a specific frequency range and may be difficult for the LNA to achieve optimal performance for a wide frequency range in the presence of blocker signals. In some instances, for example, the gain provided to the blocker signal may be larger than for the wanted channel when the LNA operates over a wide frequency range. This in turn further affects the harmonics and intermodulation prod ucts or unwanted mixing products that crosstalk with the wanted signals. Developing mechanisms that enable control of the LNA gain outside the wanted channel may be necessary in order to improve the performance of RF receivers in high bit rate data transmission applications, such as DVB-H appli cations, for example.

[0014] Further limitations and disadvantages of conventional and traditional approaches will become apparent to one of skill in the art, through comparison of Such systems with some aspects of the present invention as set forth in the remainder of the present application with reference to the drawings.

BRIEF SUMMARY OF THE INVENTION

[0015] A system and/or method is provided for an RF frontend calibration scheme using signals from a fractional-N frequency synthesizer and a received signal strength indicator (RSSI), substantially as shown in and/or described in connec tion with at least one of the figures, as set forth more com pletely in the claims.

[0016] These and other advantages, aspects and novel features of the present invention, as well as details of an illus trated embodiment thereof, will be more fully understood from the following description and drawings.

BRIEF DESCRIPTION OF SEVERAL VIEWS OF THE DRAWINGS

0017 FIG. 1A is a block diagram illustrating an exem plary mobile terminal, accordance with an embodiment of the invention.

[0018] FIG. 1B is a block diagram illustrating exemplary communication between a multi-band RF receiver and a digi tal baseband processor in a mobile terminal, in accordance with an embodiment of the invention.

[0019] FIG. 1C is a block diagram illustrating an exemplary single-chip multi-band RF receiver with an integrated LNA in each front-end, in accordance with an embodiment of the invention.

[0020] FIG. 1D is a block diagram illustrating an exemplary single-chip multi-band RF receiver with on-chip gain control processing, in accordance with an embodiment of the invention.

 $[0021]$ FIG. 2 is a flow diagram illustrating exemplary steps in the operation of a single-chip multi-band RF receiver, in accordance with an embodiment of the invention.

[0022] FIG. 3A is a diagram illustrating an exemplary fixed tuning curve for an integrated LNA in a multi-band RF receiver, in connection with an embodiment of the invention.

[0023] FIG. 3B is a diagram illustrating an exemplary dynamically controlled tuning curve for an integrated LNA in a multi-band RF receiver, in accordance with an embodiment of the invention.

0024 FIG. 4 is a block diagram illustrating an exemplary system for dynamically controlling the LNA gain, in accordance with an embodiment of the invention.

[0025] FIG. 5 is a schematic diagram illustrating an exemplary integrated LNA with tunable input load and tunable output load, in accordance with an embodiment of the inven tion.

[0026] FIGS. 6A and 6B are flow diagrams illustrating exemplary steps in the calibration of a dynamically controlled variable gain LNA for a selected desired channel, in accor dance with an embodiment of the invention.

DETAILED DESCRIPTION OF THE INVENTION

[0027] Certain embodiments of the invention may be found in a method and system for an RF front-end calibration scheme using fractional-N frequency synthesized signals and a received signal strength indicator (RSSI). Aspects of the invention may comprise a frequency synthesizer within a wireless receiver that may generate a signal that may be utilized to dynamically modify a gain in an integrated lownoise amplifier (LNA) for each selected receiver channel. The frequency-synthesized signals may be applied to at least one tunable input and/or at least one tunable output load commu nicatively coupled to the LNA. The signal generated by the frequency synthesizer may be sequentially applied to the tunable input load and the tunable output load. A logarithmic amplifier connected to the output of the LNA, may generate an RSSI signal during the calibration process, which is proportional to the signal power at the output of the LNA. The RSSI signal may be processed by a control block that subse quently generates at least one signal for controlling a tunable load communicatively coupled to the LNA.

[0028] FIG. 1A is a block diagram illustrating an exemplary mobile terminal, in accordance with an embodiment of the invention. Referring to FIG. 1A, there is shown a mobile terminal 120 that may comprise an RF receiver $123a$, an RF transmitter 123b, a digital baseband processor 129, a proces sor 125, and a memory 127. A receive antenna $121a$ may be communicatively coupled to the RF receiver 123a. A transmit antenna 121b may be communicatively coupled to the RF transmitter 123b. The mobile terminal 120 may be operated in a system, such as the cellular network and/or digital video broadcast network, for example. The U.S. application Ser. No. 1 1/385,390 filed on Mar. 21, 2006, discloses a cellular network and/or digital video broadcast network in reference to a method and system for a multi-band direct conversion CMOS mobile cellular television tuner, and is hereby incor

porated herein by reference in its entirety.

[0029] The RF receiver 123*a* may comprise suitable logic, circuitry, and/or code that may enable processing of received RF signals. The RF receiver $123a$ may enable receiving RF signals in a plurality of frequency bands. For example, the RF receiver 123a may enable receiving DVB-H transmission signals via the UHF band, from about 470 MHz to about 890 MHz, the 1670-1675 MHz band, and/or the L-band, from about 1400 MHz to about 1700 MHz, for example. Moreover, the RF receiver $123a$ may enable receiving signals in cellular frequency bands, for example. Each frequency band Sup ported by the RF receiver $123a$ may have a corresponding front-end circuit for handling low noise amplification and down conversion operations, for example. In this regard, the RF receiver $123a$ may be referred to as a multi-band receiver when it supports more than one frequency band. In another embodiment of the invention, the mobile terminal 120 may comprise more than one RF receiver $123a$, wherein each of the RF receiver $123a$ may be a single-band or a multi-band receiver.

[0030] The RF receiver $123a$ may quadrature down convert the received RF signal to a baseband frequency signal that comprises an in-phase (I) component and a quadrature (Q) component. The RF receiver $123a$ may perform direct down conversion of the received RF signal to a baseband frequency signal, for example. In some instances, the RF receiver $123a$ may enable analog-to-digital conversion of the baseband signal components before transferring the components to the digital baseband processor 129. In other instances, the RF receiver 123*a* may transfer the baseband signal components
in analog form.
[0031] The digital baseband processor 129 may comprise

suitable logic, circuitry, and/or code that may enable processing and/or handling of baseband frequency signals. In this regard, the digital baseband processor 129 may process or handle signals received from the RF receiver $123a$ and/or signals to be transferred to the RF transmitter 123b, when the RF transmitter 123b is present, for transmission to the network. The digital baseband processor 129 may also provide control and/or feedback information to the RF receiver 123a and to the RF transmitter 123b based on information from the processed signals. The digital baseband processor 129 may communicate information and/or data from the processed signals to the processor 125 and/or to the memory 127. Moreover, the digital baseband processor 129 may receive infor mation from the processor 125 and/or to the memory 127, which may be processed and transferred to the RF transmitter 123*b* for transmission to the network.

[0032] The RF transmitter $123b$ may comprise suitable logic, circuitry, and/or code that may enable processing of RF signals for transmission. The RF transmitter $123b$ may enable transmission of RF signals in a plurality of frequency bands.
Moreover, the RF transmitter $123b$ may enable transmitting signals in cellular frequency bands, for example. Each frequency band supported by the RF transmitter $123b$ may have a corresponding front-end circuit for handling amplification and up conversion operations, for example. In this regard, the RF transmitter 123b may be referred to as a multi-band transmitter when it supports more than one frequency band. In another embodiment of the invention, the mobile terminal 120 may comprise more than one RF transmitter 123b, wherein each of the RF transmitter $123b$ may be a single-band or a multi-band transmitter.

[0033] The RF transmitter $123b$ may quadrature up convert the baseband frequency signal comprising I/O components to an RF signal. The RF transmitter $123b$ may perform direct up conversion of the baseband frequency signal to a baseband frequency signal, for example. In some instances, the RF transmitter 123b may enable digital-to-analog conversion of the baseband signal components received from the digital baseband processor 129 before up conversion. In other instances, the RF transmitter $123b$ may receive baseband signal components in analog form.

[0034] The processor 125 may comprise suitable logic, circuitry, and/or code that may enable control and/or data processing operations for the mobile terminal 120. The processor 125 may be utilized to control at least a portion of the RF receiver $123a$, the RF transmitter $123b$, the digital baseband processor 129, and/or the memory 127. In this regard, the processor 125 may generate at least one signal for controlling operations within the mobile terminal 120. The processor 125 may also enable executing of applications that may be utilized by the mobile terminal 120. For example, the processor 125 may execute applications that may enable displaying and/or interacting with content received via DVB-H transmission signals in the mobile terminal 120.

[0035] The memory 127 may comprise suitable logic, circuitry, and/or code that may enable storage of data and/or other information utilized by the mobile terminal 120. For example, the memory 127 may be utilized for storing pro

cessed data generated by the digital baseband processor 129 and/or the processor 125. The memory 127 may also be utilized to store information, such as configuration informa tion, that may be utilized to control the operation of at least one block in the mobile terminal 120. For example, the memory 127 may comprise information necessary to config ure the RF receiver $123a$ to enable receiving DVB-H transmission in the appropriate frequency band.

[0036] FIG. 1B is a block diagram illustrating exemplary communication between a multi-band RF receiver and a digi tal baseband processor in a mobile terminal, in accordance with an embodiment of the invention. Referring to FIG. 1B, there is shown a multi-band RF receiver 130, a multi-channel analog-to-digital converter (ADC) 134, and a digital base band processor 132. The multi-band RF receiver 130 may comprise a UHF front-end $131a$, an L-band front-end $131b$, a VHF front-end $131c$, a baseband block $133a$, a received signal strength indicator (RSSI) block 133b, and a synthesizer 133c. The multi-band RF receiver 130, the analog-to-digital converter (ADC) 134, and/or the digital baseband processor 132 may be part of a mobile terminal, such as the mobile terminal 120 in FIG. 1A, for example.

[0037] The multi-band RF receiver 130 may comprise suitable logic, circuitry, and/or code that may enable handling of UHF, VHF, and L-band signals. The multi-band RF receiver 130 may be enabled via an enable signal, such as the signal RxEN 139*a*, for example. In this regard, enabling the multiband RF receiver 130 via the signal RxEN 139 a by a 1:10 ON/OFF ratio may allow time slicing in DVB-H while reduc ing power consumption. At least a portion of the circuitry within the multi-band RF receiver 130 may be controlled via the control interface 139b. The control interface 139b may receive information from, for example, a processor, Such as the processor 125 in FIG. 1A, or from the digital baseband processor 132. The control interface 139b may comprise more than one bit. For example, when implemented as a 2-bit interface, the control interface $139a$ may be an inter-integrated circuit (I2C) interface.

[0038] The UHF front-end $131a$ may comprise suitable logic, circuitry, and/or code that may enable low noise ampli fication and direct down conversion of UHF signals. In this regard, the UHF front-end $131a$ may utilize an integrated low noise amplifier (LNA) and mixers, such as passive mixers, for example. The UHF front-end $131a$ may communicate the resulting baseband frequency signals to the baseband block 133a for further processing.

[0039] The L-band front-end $131b$ may comprise suitable logic, circuitry, and/or code that may enable low noise ampli fication and direct down conversion of L-band signals. In this regard, the L-band front-end 131b may utilize an integrated LNA and mixers, such as passive mixers, for example. The L-band front-end $131b$ may communicate the resulting baseband frequency signals to the baseband block $133a$ for further processing.

[0040] The VHF front-end $131c$ may comprise suitable logic, circuitry, and/or code that may enable low noise ampli fication and direct down conversion of VHF signals. In this regard, the VHF front-end $131c$ may utilize an integrated low noise amplifier (LNA) and mixers, such as passive mixers, for example. The VHF front-end $131c$ may communicate the resulting baseband frequency signals to the baseband block 133a for further processing. The multi-band RF receiver 130 may enable one of the UHF front-end $131a$, the L-band frontend 131b, and the VHF front-end 131c based on current communication conditions.

[0041] The synthesizer 133 c may comprise suitable logic, circuitry, and/or code that may enable generating the appro priate local oscillator (LO) signal for performing direct down conversion in the UHF front-end $131a$, the L-band front-end 131b, or the VHF front-end 131c. Since the synthesizer 133c may enable fractional multiplication of a source frequency when generating the LO signal, a large range of crystal oscil lators may be utilized as a frequency source for the synthe sizer $133c$. This approach may enable the use of an existing crystal oscillator in a mobile terminal PCB, thus reducing the number of external components necessary to support the operations of the multi-band RF receiver 130, for example. The synthesizer 133 may generate a common LO signal for the UHF front-end 131a, the L-band front-end 131b, and the VHF front-end $131c$. In this regard, the UHF front-end $131a$, the L-band front-end $131b$, and the VHF front-end $131c$ may enable dividing the LO signal in order to generate the appropriate signal to perform down conversion from the UHF band, the L-band, and the VHF band respectively. In some instances, the synthesizer 133 may have at least one inte grated voltage controlled oscillator (VCO) for generating the LO signal. In other instances, the VCO may be implemented outside the synthesizer 133.

[0042] The baseband block $133a$ may comprise suitable logic, circuitry, and/or code that may enable processing of I/O components generated from the direct down conversion operations in the UHF front-end 131a, L-band front-end 131b, and the VHF front-end 131 c . The baseband block 133 a may enable amplification and/or filtering of the I/Q components in analog form. The baseband block 133a may commu nicate the processed I component, that is, signal 135a, and the processed Q component, that is, signal $135c$, to the multichannel ADC 134 for digital conversion.
[0043] The RSSI block 133*b* may comprise suitable logic,

circuitry, and/or code that may enable measuring the strength, that is, the RSSI value, of a received RF signal, whether UHF, L-band, or VHF signal. The RSSI block 133b may be implemented based on a logarithmic amplifier, for example. The RSSI measurement may be performed, for example, after the received RF signal is amplified in the UHF front-end $131a$, the L-band front-end $131b$, or the VHF front-end $131c$. The RSSI block 133b may communicate the analog RSSI mea surement, that is, signal 135e, to the multi-channel ADC 134 for digital conversion.

0044) The multi-channel ADC 134 may comprise suitable logic, circuitry, and/or code that may enable digital conver sion of signals $135a$, $135c$, and/or $135e$ to signals $135b$, $135d$, and/or 135frespectively. In some instances, the multi-channel ADC 134 may be integrated into the multi-band RF receiver 130 or into the digital baseband processor 132.

[0045] The digital baseband processor 132 may comprise suitable logic, circuitry, and/or code that may enable processing and/or handling of baseband frequency signals. In this regard, the digital baseband processor 132 may be the same or substantially similar to the digital baseband processor 129 described in FIG. 1A. The digital baseband processor 132 may enable generating at least one signal, such as the signals AGC BB 137 a and AGC RF 137 b , for adjusting the operations of the multi-band RF receiver 130. For example, the signal AGC_BB $137a$ may be utilized to adjust the gain provided by the baseband block $133a$ on the baseband frequency signals generated from the UHF front-end 131a, the L-band front-end 131b, or the VHF front-end 131c. In another example, the signal AGC_RF $137b$ may be utilized to adjust the gain provided by an integrated LNA in the UHF front-end 131a, the L-band front-end 131b, or the VHF front-end $131c$. In this regard, the signal AGC_RF $137b$ may be utilized to adjust the gain during a calibration mode, for example. In another example, the digital baseband processor 132 may generate at least one control signal or control information communicated to the multi-band RF receiver 130 via the control interface 139b for adjusting operations within the multi-band RF receiver 130.

[0046] FIG. 1C is a block diagram illustrating an exemplary single-chip multi-band RF receiver with an integrated LNA in each front-end, in accordance with an embodiment of the invention. Referring to FIG. 1C, there is shown a single-chip multi-band RF receiver $140a$ that may comprise a UHF frontend 148a, an L-band front-end 148b, a VHF front-end 148c, a baseband block 164, a logarithmic amplifier 172, a digital frequency synthesizer 189, a Σ - Δ fractional-N synthesizer 174, a VCO block 176, a digital interface 160, an ADC 162, an oscillator 180, and a buffer 182.

[0047] The single-chip multi-band RF receiver $140a$ may be fabricated using any of a plurality of semiconductor manu facturing processes, for example, complimentary metal-oxide-semiconductor (CMOS) processes, bipolar CMOS (BiC MOS), or Silicon Germanium (SiGe). The single-chip multi band RF receiver $140a$ may be implemented using differential structures to minimize noise effects and/or sub strate coupling, for example. The single-chip multi-band RF receiver $140a$ may utilize low drop out (LDO) voltage regulators to regulate and clean up on-chip voltage supplies. In this regard, the LDO voltage regulators may be utilized to transform external voltage sources to the appropriate on-chip voltages.

[0048] When the single-chip multi-band RF receiver $140a$ is implemented utilizing a CMOS process, some design considerations may include achieving low noise figure (NF) val ues, wide-band operation, high signal-to-noise ration (SNR). performing DC offset removal, achieving high input second order and third-order intercept points (IIP2 and IIP3), and/or reducing I/O mismatch, for example.

[0049] The single-chip multi-band RF receiver $140a$ may receive UHF signals via a first antenna 142a, a UHF filter 144a, and a first balum 146a. The UHF filter 144a enables band pass filtering, wherein the band pass may be about 470 to about 702 MHZ for cellular signals, for example, or about 470 to about 862 MHz, for other types of received signals, for example. The balum $146a$ enables balancing the filtered signals before being communicated to the UHF front-end 148a. [0050] The single-chip multi-band RF receiver $140a$ may receive L-band signals via a second antenna 142b, an L-band filter 144b, and a second balum 146b. The L-band filter $144b$ enables band pass filtering, wherein the band pass may be about 1670 to about 1675 MHz for signals in US systems, for example, or about 1450 to about 1490 MHz, for signals in European systems, for example. The balum 146b enables balancing the filtered signals before being communicated to the L-band front-end 148a.

[0051] The single-chip multi-band RF receiver $140a$ may receive VHF signals via a third antenna 142c, a VHF filter 144c, and a third balum 146c. The VHF filter 144c enables band pass filtering, wherein the band pass may be about 174 to about 240 MHz for signals in US systems, for example. The balum $146c$ enables balancing the filtered signals before being communicated to the VHF front-end $148c$. In some instances, antennas $142a$, $142b$ and $142c$ may be implemented utilizing a single antenna communicatively coupled to the single-chip multi-band RF receiver $140a$ that may support receiving radio signals operating in the UHF, L-band, and/or VHF frequencies, for example.

[0052] The UHF front-end $148a$ may comprise a variable gain low noise amplifier (LNA) $150a$, a mixer $152a$, a mixer 154a, and a LO signal divider 156a. The variable gain LNA 150a may comprise suitable logic and/or circuitry that may enable amplification of the UHF signals received. Matching between the output of the balum $146a$ and the input of the variable gain LNA $150a$ may be achieved by utilizing off-chip series inductors, for example. The variable gain LNA 150a may implement continuous gain control by current steering that may be controlled by a replica scheme within the variable gain LNA $150a$ may be adjusted via the signal AGC_RF $137b$, for example. In this regard, the gain of the variable gain LNA $150a$ may be adjusted during a calibration mode for each selected desired channel of operation within the frequency range provided by the UHF front-end 148a, for example.

[0053] The mixers $152a$ and $154a$ may comprise suitable logic and/or circuitry that may enable generating in-phase (I) and quadrature (Q) components of the baseband frequency signal based on direct down conversion of the amplified received UHF signal with the quadrature signals 186I and 186Q generated by the divider block 156a. The mixers 152a and 154a may be passive mixers in order to achieve high linearity and/or low flicker noise, for example. The LO signal divider $156a$ may comprise suitable logic, circuitry, and/or code that may enable dividing of the LO signal 186 by a factor of 2 (\cdot /2) or a factor of 3 (\cdot /3) and at the same time provide quadrature outputs 186I and 186O, wherein 186I and 186O have 90 degrees separation between them. The factor of 3 division may be used when the received UHF signal band is about 470 to about 600 MHz, for example. The factor of 2 division may be used when the received UHF signal band is about 600 to about 900 MHz, for example. The I/Q components generated by the mixers $152a$ and $154a$ may be communicated to the baseband block 164.

[0054] The L-band front-end $148b$ may comprise a variable gain LNA 150*b*, a mixer 152*a*, a mixer 154*a*, and a LO signal generator 158. The variable gain LNA 150*a* may comprise suitable logic and/or circuitry that may enable amplification of the L-band signals received. Matching between the output of the balum $146b$ and the input of the variable gain LNA $150b$ may be achieved by utilizing off-chip series inductors, for example. The variable gain LNA 150b may implement continuous gain control by current steering that may be con trolled by a replica scheme within the variable gain LNA 150*b*. The gain of the variable gain LNA 150*b* may be adjusted via the signal AGC_RF 137b, for example. In this regard, the gain of the variable gain LNA $150b$ may be adjusted during a calibration mode for each selected desired channel of operation within the frequency range provided by the L-band front-end 148b, for example.

[0055] The mixers $152b$ and $154b$ may comprise suitable logic and/or circuitry that may enable generating I/Q components of the baseband frequency signal based on the direct down conversion of the amplified received L-band signal with the LO signals 158I and 158O generated by the LO generator block 158. The mixers $152b$ and $154b$ may be passive mixers in order to achieve high linearity and/or low flicker noise, for example. The LO signal generator 158 may comprise suitable logic, circuitry, and/or code that may enable generation of quadrature LO signals 158I and 158O, that is, signals with 90 degree phase split between them, from the LO signal 186. The I/Q components generated by the mixers $152b$ and $154b$ may be communicated to the baseband block 164.

[0056] The VHF front-end $148c$ may comprise a variable gain LNA 150c, a mixer 152c, a mixer 154c, and a LO signal divider 156b. The variable gain LNA 150c may comprise suitable logic and/or circuitry that may enable amplification of the VHF signals received. Matching between the output of the balum 146c and the input of the variable gain LNA 150c may be achieved by utilizing off-chip series inductors, for example. The variable gain LNA $150c$ may implement continuous gain control by current steering that may be con trolled by a replica scheme within the variable gain LNA 150 c . The gain of the variable gain LNA 150 c may be adjusted via the signal AGC_RF $137b$, for example. In this regard, the gain of the variable gain LNA $150c$ may be adjusted during a calibration mode for each selected desired channel of operation within the frequency range provided by the VHF front-end $148c$, for example.

[0057] The mixers $152c$ and $154c$ may comprise suitable logic and/or circuitry that may enable generating in-phase (I) and quadrature (Q) components of the baseband frequency signal based on direct down conversion of the amplified received VHF signal with the quadrature signals 187I and 187Q generated by the divider block 156*b*. The mixers 152*c* and 154*c* may be passive mixers in order to achieve high linearity and/or low flicker noise, for example. The LO signal divider $156b$ may comprise suitable logic, circuitry, and/or code that may enable dividing of the LO signal **186** by a factor of 6 (:/6) or a factor of 8 (:/8) and at the same time provide quadrature outputs 187I and 187Q, wherein 187I and 187Q are 90 degrees out of phase with each other. The factor of 8 division may be used when the received VHF signal band is about 174 to about 200 MHz, for example. The factor of 6 division may be used when the received VHF signal band is about 200 to about 240 MHz, for example. The I/O compo nents generated by the mixers $152c$ and $154c$ may be communicated to the baseband block 164.

0058. The logarithmic amplifier 172 may comprise suit able logic, circuitry, and/or code that may enable generation of a wideband, received signal strength indicator (RSSI) sig nal, such as the signal 135e, based on the output of the vari able gain LNA $150a$, the variable gain LNA $150b$, or the variable gain LNA $150c$, for example. The RSSI signal indicates the total amount of signal power that is present at the output of the LNA, for example. The RSSI signal may be utilized by, for example, the digital baseband processor 132 in FIG. 1B, to adjust the gain of a variable gain LNA in the presence of RF interference to achieve NF and/or linearity performance that meets blocking and/or intermodulation specifications, for example. In this regard, interference may refer to blocker signals, for example. Blocker signals may be unwanted signals infrequency channels outside the wanted or desired channel that may disturb the reception of the wanted signals. This effect may be a result of blockers generating large signals within the receiver path. These large signals may introduce harmonics, intermodulation products, and/or unwanted mixing products that crosstalk with the wanted signals.

[0059] The baseband block 164 may comprise an in-phase component processing path and a quadrature component pro cessing path. The in-phase processing path may comprise at least one programmable gain amplifier (PGA) $166a$, a base-band filter $168a$, and at least one PGA $170a$. The quadrature component processing path may comprise at least one PGA 166b, a baseband filter 168b, and at least one PGA 170b. The PGAs 166a, 166b, 170a, and 170b may comprise suitable logic, circuitry, and/or code that may enable amplification of the down converted components of the baseband frequency signal generated by the RF front-end. The gain of the PGAs 166a, 166b. 170a, and 170b may be digitally programmable. In addition, at the output of the PGAs 166a and 166b, a programmable pole may be utilized to reduce linearity requirements for the baseband filters $168a$ and $168b$ respectively. Since the static and time-varying DC offset may saturate the operation of the single-chip multi-band RF receiver 140a, the PGAs 166a, 166b, 170a, and 170b may utilize DC servo loops to address DC offset issues. The gain of the PGAs 166a, 166b, 170a, and/or 170b may be controlled via the AGC BB signal 137a, for example. In this regard, the ADC 162 may be utilized to provide digital control of the PGAs 166a, 166b, 170a, and/or 170b when the AGC_BB signal 137a is an analog signal.

[0060] The baseband filters $168a$ and $168b$ may comprise suitable logic, circuitry, and/or code that may enable channel selection, for example. Channel selection may be performed by filters, such as an Nth order lowpass Chebyschev filter implemented by active integrators in a leapfrog configura tion, for example. For the correct tuning of the characteristics of the filters, an on-chip auto-calibration loop may be acti vated upon power-up. The auto-calibration loop may set up the corner frequency to the correct Vale required to meet the requirements of the communications standard for which the receiver is designed. For DVB-T/DVB-H, the value f_o of the filter response may be set to a value from 2.5 to 4 MHz thus supporting the different channel bandwidths of 5-8 MHz specified by DVB-T/DVB-H standards. During auto-calibra tion, a tone at the appropriate $f_{-3,db}$ may be generated on-chip and may be applied at the input of the baseband filters 168a and 168b for comparison with the filter output of a root-mean squared (RMS) detector. A digitally controlled loop may be utilized to adjust the baseband filter bandwidth until the out put of the baseband filter and the RMS detector are the same.

[0061] The Σ - Δ fractional-N synthesizer 174 may comprise suitable logic, circuitry, and/or code that may enable LO generation that may be independent of the reference crystal frequency, such as the crystal 178, for example. In this regard, the synthesizer 174 may generate a signal, such as the signal 190, for example, to control the operation of the VCO block 176 and therefore the generation of the LO signal 186. Since the synthesizer 174 may enable fractional synthesis, the single-chip multi-band RF receiver $140a$ may utilize the same crystal utilized by other operations in the mobile terminal while maintaining fine tuning capability. The synthesizer 174 may receive a reference frequency signal from the crystal 178 via an oscillator 180, for example. The output of the oscillator 180 may also be buffered by the buffer 182 to generate a clock signal 184, for example.

[0062] The synthesizer 174 may also be utilized to generate a signal. Such as a tone, for example, to calibrate the inte grated LNAs in the UHF front-end $148a$, the L-band frontend $148b$, or the VHF front-end $148c$, when a new desired channel is selected for operation. In this regard, the synthe sizer 174 may generate a signal with a frequency that corre sponds to the desired channel that is selected. The ability of the synthesizer 174 to provide fine tuning capabilities enables the generation of the appropriate signal frequency for a large range of desired channels in the operation of the single-chip multi-band RF receiver 140a.

0063. The VCO block 176 may comprise suitable logic, circuitry, and/or code that may enable generating the LO signal 186 utilized by the UHF front-end $148a$, the L-band front-end 148*b*, the VHF front-end 148*c* for direct down conversion of the received RF signals and by the digital frequency synthesizer 189. The VCO block 176 may comprise at least one VCO, wherein each VCO may have cross coupled NMOS and PMOS devices and metal-oxide-semi conductor (MOS) varactors in an accumulation mode for tuning. In this regard, a switched varactor bank may be utilized for providing coarse tuning. The VCO block 176 may provide a range of about 1.2 to about 1.8 GHz when implemented utilizing two VCOs, for example. When more than one VCO is utilized in implementing the VCO block 176, selecting the proper VCO for generating the LO signal 186 may be based on the type of RF signal being received by the single-chip multi-band RF receiver 140a.

 $[0064]$ The digital interface 160 may comprise suitable logic, circuitry, and/or code that may enable controlling cir cuitry within the single-chip multi-band RF receiver 140a. The digital interface 160 may comprise a plurality of registers for storing control and/or operational information for use by the single-chip multi-band RF receiver $140a$. The digital interface 160 may enable receiving the signal RxEN $139a$ that may be utilized to perform 1:10 ON/OFF ratio time slicing in DVB-H while reducing power consumption. Moreover, the digital interface 160 may enable receiving the control inter face 139b from, for example, a processor, such as the proces sor 125 in FIG. 1A, or from the digital baseband processor 132 in FIG. 1B. The control interface 139b may comprise more than one bit. The control interface 139b may be utilized to control the synthesis operations of the synthesizer 174 and/or the filtering operations of the baseband filters $168a$ and 168b. The control interface 139b may also be utilized to adjust the bias of circuits within the single-chip multi-band RF receiver $140a$, such as those of the variable gain LNAs 150a, 150b, and 150c the PGAs 166a, 166b, 170a, and 170b, and/or the baseband filters 168a and 168b, for example.

[0065] The digital frequency synthesizer 189 may comprise suitable logic, circuitry, and/or code that may enable generation of a reference signal based on a clock timing signal, and on a control input signal. In various embodiments of the invention, the digital frequency synthesizer 189 may implement a look up table (LUT) function wherein a given clock timing signal and control input signal combination may correspond to a frequency, phase, and/or magnitude for a generated reference signal. Data utilized for the LUT function may be stored and/or retrieved from the memory 127 in FIG. 1A, for example. In other embodiments of the invention, the digital frequency synthesizer 189 may comprise an over sampling digital to analog conversion (DAC) function in which the digital frequency synthesizer 189 performs digital sampling of the clock timing signal. A rate of digital sampling may be determined based on the control input signal.

[0066] FIG. 1D is a block diagram illustrating an exemplary single-chip multi-band RF receiver with on-chip gain control processing, in accordance with an embodiment of the invention. Referring to FIG. 1D, there is shown a single-chip multi-band RF receiver $140b$ that may differ from the single-chip multi-band RF receiver $140a$ in FIG. 1C in that a gain control block 186 may be integrated into the single-chip multi-band RF receiver $140b$. The gain c comprise suitable logic, circuitry, and/or code that may enable on-chip gain adjustment for the variable gain LNAS 150a, 150b, and 150c and for the PGAS 166a, 166b, 170a, and 170b. In this regard, the gain control block 186 may receive the RSSI signal $135e$ and may generate the signals AGC_BB 137 a and AGC_RF 137 b , for example.

[0067] FIG. 2 is a flow diagram illustrating exemplary steps in the operation of a single-chip multi-band RF receiver, in accordance with an embodiment of the invention. Referring to FIG. 2, there is shown a flow diagram 200. In step 204, after start step 202, a single-chip multi-band RF receiver, such as the single-chip multi-band RF receiver $140a$ and $140b$, for example, may be powered up in a mobile terminal. In step 206, the RF receiver may be enabled via signal RxEN $139a$ and control and/or operational information may be pro grammed into the digital interface 160 via the control inter face 139b for use by the RF receiver during operation.

[0068] In step 208, an operating frequency band may be selected via the control interface 139b. In this regard, if the mobile terminal is to receive UHF signals, the UHF front-end 152a, the baseband block 164, and/or the synthesizer 174 may be configured for receiving and processing UHF signals in the RF receiver. If the mobile terminal is to receive L-band signals, the L-band front-end 152b, the baseband block 164, and/or the synthesizer 174 may be configured for receiving and processing L-band signals in the RF receiver. If the mobile terminal is to receive VHF signals, the VHF front-end $152c$, the baseband block 164 , and/or the synthesizer 174 may be configured for receiving and processing VHF signals in the RF receiver. In step 210, the synthesizer 174 and the VCO block 176 may be utilized to generate the appropriate value for the LO signal 186 base on the band of operation.

[0069] In step 214, the RF receiver may measure an RSSI for the output of a variable gain LNA of the currently operating front-end for determining the amount of adjusting or backing off that may be required from the variable gain LNA. The RSSI measurement and corresponding gain adjustment may be performed during a calibration mode that occurs after a new desired channel of operation is selected. The amount of adjusting may be determined off-chip or on-chip as described in FIGS. 1D and 1E respectively. Adjusting the LNA gain based on the RSSI may also be done during and simulta neously with the reception of the broadcast signal, for example the normal 1:10 DVB-H reception mode after step 216. Other measurements may be performed in the front-end circuits 148a and 148b and/or the baseband block 164 that may be utilized to adjust biasing levels within the RF receiver. In step 216, the front-end circuits $148a$ and $148b$ and/or the baseband block 164 may be adjusted, when necessary, based on measurements performed in step 214. In step 216, during DVB-H operation, the RF receiver may be enabled utilizing a 1:10 ON/OFF ratio for time slicing in DVB-H and to reduce power consumption. After step 216, the process may proceed to end step 218.

[0070] FIG. 3A is a diagram illustrating an exemplary fixed tuning curve for an integrated LNA in a multi-band RF receiver, in connection with an embodiment of the invention. Referring to FIG. 3A, there is shown a graph 300a that cor responds to the gain of an integrated LNA in a RF front-end with a fixed LNA tuning curve 306. The integrated LNA operates in the range comprising the frequencies f1 through f2, for example. For UHF signals, f1 may be approximately 470 MHz and f2 may be approximately 890 MHz, for example. The fixed LNA tuning curve 306 may provide dif ferent gains for signals with different frequencies over the entire integrated LNA operating frequency range. Also shown in FIG. 3A are a dashed bar that corresponds to a desired channel signal 302 at frequency fdc and a blank bar that corresponds to an interference or blocking signal 304 at fre quency fi. The difference in height between the bar that cor responds to the desired channel signal 302 and the bar that corresponds to the interference signal 304 may indicate a relative difference in signal strength, for example.

[0071] In some instances, the gain provided by the fixed LNA tuning curve 306 associated to the desired channel sig nal 302 and to the interference signal 304 may be such that the signal strength of the interference signal 304, after its corre sponding gain is applied, may be comparable to, or even larger than, the signal strength of the desired channel signal 302, after its corresponding gain is applied. When this occurs, the presence of the amplified interference signal 304 in the operating frequency range of the integrated LNA may affect the harmonics and intermodulation products or unwanted mixing products that causes crosstalk with the desired chan nel signal 302.

[0072] FIG. 3B is a diagram illustrating an exemplary dynamically controlled tuning curve for an integrated LNA in a multi-band RF receiver, in accordance with an embodiment of the invention. Referring to FIG. 3B, there is shown a graph $300b$ that corresponds to the gain of an integrated LNA in a RF front-end with a dynamically controlled tuning curve 308. The integrated LNA operates in the range comprising the frequencies f1 through f2, for example. The dynamically controlled tuning curve 308 may provide different gains for signals with different frequencies over a portion of the inte grated LNA operating frequency range. For example, the dynamically controlled tuning curve 308 is shown to provide different gains for signals with corresponding frequencies in the range comprising the frequencies f3 through f4. A signal with a corresponding frequency outside the range provided by the dynamically controlled tuning curve 308 would be attenu ated by the integrated LNA. In this regard, the frequency range for the dynamically controlled tuning curve 308 may be programmed to enable the integrated LNA to select a fre quency range that amplifies the desired channel 302 and attenuates the interference signal 304.

[0073] FIG. 4 is a block diagram illustrating an exemplary system for dynamically controlling the LNA gain, in accor dance with an embodiment of the invention. Referring to FIG. 4, there is shown a dynamically controlled integrated LNA system 400 that may comprise a tunable input load 402, an LNA 404, a tunable output load 406, a crystal oscillator (XTAL) 408, a phase locked loop (PLL) 410, a local oscillator (LO) generator 412, Switches 414, a logarithmic amplifier 416, and a control block 418.

[0074] The LNA 404 may correspond to an integrated LNA such as the variable gain LNAs $150a$, $150b$, and $150c$ described in FIGS. 1C-1D, for example. The logarithmic amplifier 416 may provide the same or substantially similar RSSI measuring operations as the logarithmic amplifier 172
described in FIGS. 1C-1D, for example. The XTAL 408 may be a reference crystal frequency such as the crystal 178 described in FIGS. 1C-1D, for example.

[0075] The PLL 410 may comprise suitable logic, circuitry, and/or code that may enable generating a reference signal that may be utilized by the LO generator 412. The operations provided by the PLL 410 may the same or substantially similar to those provided by the Σ - Δ fractional-N synthesizer 174 described in FIGS. 1C-1D, for example. In the present embodiment, by using a Σ - Δ fractional-N synthesizer, practically any frequency within the wanted range may be generated using a wide range of XTAL reference frequencies, which may allow optimization of the LNA tuning at arbitrary ranges within the wanted band of operation. The LO genera tor 412 may comprise suitable logic, circuitry, and/or code that may enable the generation of a single tone or single frequency signal that may be utilized to calibrate the gain provided by the tuning curve of the LNA 404 . The operations provided by the LO generator 412 may be the same or substantially similar to those provided by the VCO block 176 and/or the LO signal dividers 156a and 156b described in FIGS. 1C-1D, for example.

[0076] The tunable input load 402 may comprise suitable logic, circuitry, and/or code that may enable dynamically controlling of a tuning curve associated with the LNA 404. In this regard, the tuning curve may be dynamically controlled by the digital control signal 420 generated by the control block 418. The tunable input load 402 may be implemented using a capacitor bank, for example.

[0077] The tunable output load 406 may comprise suitable logic, circuitry, and/or code that may enable dynamically controlling of the tuning curve associated with the LNA 404. In this regard, the tuning curve may be dynamically con trolled by the digital control signal 420 generated by the control block 418. The tunable output load 406 may be implemented using a capacitor bank, for example.
 [0078] The control block 418 may comprise suitable logic.

circuitry, and/or code that may enable generation of the digital control signal 420 to adjust the tuning curve of the LNA 404 by adjusting the tunable input load 402 and/or the tunable output load 406. In an embodiment of the invention, if the control block 418 is integrated into the RF receiver, the con trol block 418 may correspond to the gain control block 188 described in FIG. 1D. In this regard, the signal AGC RF $137b$ may correspond to the digital control signal 420, for example. [0079] In another embodiment of the invention, the control block 418 may comprise an ADC 422 and a digital control 424. In this regard, the ADC 422 may be the same or substan tially similar to the ADC 134 described in FIG. 1B and the digital control 424 may be implemented within the digital baseband processor 132 also as described in FIG. 1B. The ADC 422 may comprise Suitable logic, circuitry, and/or code that may enable analog-to-digital conversion of either an RSSI measurement from the logarithmic amplifier 416 or a processed I component, such as signal $135a$ in FIGS. 1B-1D, for example. In another embodiment of the invention, the ADC 422 may enable analog-to-digital conversion of either an RSSI measurement from the logarithmic amplifier 416 or a processed Q component, such as signal $135c$ in FIGS. 1B-1D. The digital control 424 may comprise suitable logic, circuitry, and/or code that may enable generation of a digital control signal, such as the digital control signal 420, to adjust the tunable input load 402 and/or the tunable output load 404. [0080] The switches 414 may comprise suitable logic, circuitry, and/or code that may enable selecting whether to intro duce the single tone or single frequency signal generated by the LO generator 412 to the input of the tunable input load 402 and/or to the output of the LNA 404 to generate an RSSI measurement. The single tone or single frequency signal may be introduced during a calibration mode. For example, for each new selected desired channel of operation, the RF receiver may perform a calibration or tuning curve adjust ment of the LNA 404 before normal gain operations. At least one signal may be utilized to select whether the single tone or single frequency signal is to be introduced to the input of the tunable input load 402, to the output of the LNA 404, or to both.

[0081] In operation, the dynamically controlled integrated LNA system 400 may be operated in a calibration mode to adjust the tuning curve of the LNA 404 for a currently selected desired channel of operation. The XTAL 408 may generate a reference signal that may be utilized by the PLL 410 to generate a signal that in turn may be utilized by the LO generator 412 to generate the single tone or single frequency signal that corresponds to the currently selected operating channel. The switches 414 may be utilized to introduce the singletone to the input of the tunable input load 402 and/or to the output of the LNA 404.

[0082] The output generated by the LNA 404 may be measured by the logarithmic amplifier 416 to generate an RSSI signal. The RSSI signal may be communicated to the control block 418 where the ADC 422 may digitize it. The digitized RSSI signal may be communicated to the digital control 424 where the digital control signal 420 may be generated to adjust the tunable input load 402 and/or the tunable output load 406 to achieve the appropriate tuning curve for the cur rently selected desired channel of operation. Once the tuning curve is properly adjusted, the dynamically controlled inte grated LNA system 400 may operate in a normal mode of operation.

[0083] FIG. 5 is a schematic diagram illustrating an exemplary integrated LNA with tunable input load and tunable output load, in accordance with an embodiment of the inven tion. Referring to FIG. 5, there is shown an integrated LNA 500 with a tunable input capacitor bank (Cb1) 508 and a tunable output capacitor bank (Cb2) 518. The integrated LNA 500 may comprise a first transistor (M1) 512, a second tran sistor (M2) 514, an inductor Ls 510, and an inductor Ld 516. The LNA500 may also be implemented as a fully differential, that is, a balanced structure, and may communicate with PCB components, such as the balums $146a$, $146b$, and $146c$ illustrated in FIGS. 1C-1D, via PCB traces that comprise series inductive components such as L_{PCB} 506, for example. The U.S. application Ser. No. 1 1/385,423, filed on Mar. 21, 2006, discloses a method and system for mobile cellular television tuner utilizing current-steering variable gain at RF, and is hereby incorporated herein by reference in its entirety.

I0084. The tunable input capacitor bank (Cb1) 508 may comprise a plurality of capacitors wherein the appropriate capacitance value for the Cb1 508 may be selected by the digital control signal 420 described in FIG. 4 to adjust the tuning curve of the LNA 500 in accordance with a currently selected desired channel of operation. The Cb1 508 may be implemented in parallel to the LS 510 with one end of the capacitors connected to the gate of M1512 and the other end connected to GND 502. Similarly, the tunable output capaci tor bank (Cb2) 518 may comprise a plurality of capacitors wherein the appropriate capacitance value selected for the Cb2 518 may be selected by the digital control signal 420 to adjust the tuning curve of the LNA 500 in accordance with a currently selected desired channel of operation. The Cb2 518 may be implemented in parallel to the Ld 516 with one end of the capacitors connected to the drain of M2514 and the other end connected to Vdd 504.

[0085] Also shown in FIG. 5 are the logarithmic amplifier 416, the LO generator 412, and the switches 414 described in FIG. 4. The switches 414 may comprise a first RF switch $414a$ and a second RF switch $414b$. The first RF switch $414a$ and the second RF switch $414b$ may comprise suitable logic, circuitry, and/or code that may enable selecting whether to introduce the single tone or single frequency for calibrating or adjusting the LNA 500 tuning curve at the gate of M1512, at the drain of M2 514, or at both locations. In this regard, the first RF switch $414a$ enables introducing the single tone or single frequency signal at the drain of M2 514, while the second RF switch 414b enables introducing the single tone or single frequency signal at the gate of $M1$ 512, for example.
The output of the LNA 500, that is, the drain of $M2$ 514, may be measured by the logarithmic amplifier 416 to generate an RSSI signal that may be utilized to adjust the Cb1 508 and/or the Cb2 518 to dynamically control the tuning curve of the LNA 500 to optimize the gain behavior of the LNA 500 for a currently selected desired operating channel.

[0086] FIGS. 6A and 6B are flow diagrams illustrating exemplary steps in the calibration of a dynamically controlled variable gain LNA for a selected desired channel, in accor dance with an embodiment of the invention. Referring to FIG. 6A, there is shown a flow chart 600. In step 604, a desired channel of operation is selected. In step 606, during the cali bration mode, a single tone or single frequency signal that corresponds to the selected desired channel may be generated by the LO generator 412 to generate an output from the dynamically controlled variable gain LNA.

 $[0087]$ In step 608, the single tone or single frequency signal may be applied to the input of the tunable input load 402 or to the output of the dynamically controlled variable gain LNA. In the illustrative example in FIG. 5, the input of the tunable input load 402 corresponds to one end of the Cb1 508 while the output of the dynamically controlled variable gain LNA corresponds to one end of the Cb2 518. At least one signal may be generated to determine where to introduce the single tone or single frequency signal. In this regard, the switches 414 may be configured based on the signals generated.

[0088] In step 610, the output of the dynamically controlled variable gain LNA may be measured by the logarithmic amplifier 416 to determine an RSSI value. In step 612, the control block 418 may generate the digital control signal 420 to adjust the tunable input load 402 or the tunable output load 406. In step 614, the calibration operation may be completed and the single-chip multi-band RF receiver $140a$ may enable a general or normal gain mode of operation for the dynami cally controlled variable gain LNA. In step 616, the single chip multi-band RF receiver $140a$ may determine whether to select a new desired operating channel. When the new desired channel is selected, the process may proceed to step 604. In instances where the new desired channel is not selected, the process may proceed to end step 618.

[0089] In another embodiment of the invention, the calibration operation may require a new reading of the dynamically controlled variable gain LNA output to generate an updated RSSI value for each adjustment made to the tunable input load 402 and/or the tunable output load 406. In this regard, the steps 610 and 612 may be repeated iteratively multiple times until the tuning curve of the dynamically controlled variable gain LNAachieves a determined performance for the selected desired channel of operation. This may be achieved when the RSSI reading indicates that the gain is maximized for the available tuning range for the specific LO input injected at the input or output load. When the tuning curve achieves the determined performance, the process may again proceed to step 614 where the single-chip multi-band RF receiver $140a$ may terminate the calibration operation and may proceed to enable a general or normal gain mode of operation.
[0090] Referring to FIG. 6B, there is shown a flow diagram

 620 . In step 624 , the single tone or single frequency signal generated by the LO generator 412 that corresponds to the selected desired channel may be applied to a first tunable load communicatively coupled to the dynamically controlled vari able gain LNA. The first tunable load may be the input or the output load. In step 626, the output of the dynamically con trolled variable gain LNA may be measured by the logarith mic amplifier 416 to determine an RSSI value. In step 628, the control block 418 may determine whether the RSSI measure ment indicates that a maximum gain is achieved by the dynamically controlled variable gain LNA. When a maxi mum gain is not achieved, the process may proceed to step 630. In step 630, the control block 418 may generate a digital control signal to adjust the first tunable load.

[0091] Returning to step 628, when the RSSI measurement indicates that a maximum gain is achieved, the process may proceed to step 632 . In step 632 , the calibration process may require that a second tunable load communicatively coupled to the dynamically controlled variable gain LNA also be calibrated. The second tunable load may be the input or output load not yet calibrated. When a second tunable is to be cali brated, the process may proceed to step 634. In step 634, the single tone or single frequency signal generated by the LO generator 412 that corresponds to the selected desired chan nel may be applied to the second tunable load of the dynami cally controlled variable gain LNA. After step 634, the pro cess may proceed to steps 626 and 628. When a maximum gain is not achieved in Step 628, the process may proceed to step 630 where the control block 418 may generate a digital control signal to adjust the second tunable load.

[0092] Returning to step 632, when the calibration process does not require that a second tunable load communicatively coupled to the dynamically controlled variable gain LNA be calibrated or when calibration of the second tunable load has been completed, the process may proceed to step 636. In step 636, the single-chip multi-band RF receiver $140a$ may terminate the calibration operation and may proceed to enable a general or normal gain mode of operation.

[0093] Accordingly, the present invention may be realized in hardware, software, or a combination of hardware and software. The present invention may be realized in a central ized fashion in at least one computer system, or in a distrib uted fashion where different elements are spread across sev eral interconnected computer systems. Any kind of computer system or other apparatus adapted for carrying out the meth ods described herein is suited. A typical combination of hard ware and software may be a general-purpose computer system with a computer program that, when being loaded and executed, controls the computer system such that it carries out the methods described herein.

[0094] The present invention may also be embedded in a computer program product, which comprises all the features enabling the implementation of the methods described herein, and which when loaded in a computer system is able to carry out these methods. Computer program in the present context means any expression, in any language, code or nota tion, of a set of instructions intended to cause a system having an information processing capability to perform a particular function either directly or after either or both of the following: a) conversion to another language, code or notation; b) repro duction in a different material form.

[0095] While the present invention has been described with reference to certain embodiments, it will be understood by those skilled in the art that various changes may be made and equivalents may be substituted without departing from the scope of the present invention. In addition, many modifications may be made to adapt a particular situation or material to the teachings of the present invention without departing from its scope. Therefore, it is intended that the present inven tion not be limited to the particular embodiment disclosed, but that the present invention will include all embodiments falling within the scope of the appended claims.

1-22. (canceled)

23. A method for processing signals in a wireless device, the method comprising:

- generating a signal via an on-chip frequency synthesizer in a multi-band wireless receiver chip; and
- dynamically modifying a gain in a low-noise amplifier (LNA) within said multi-band wireless receiver chip for a receiver channel, by applying a control signal based on said generated signal to at least one tunable load com municatively coupled to said LNA.

24. The method according to claim 23, comprising apply ing said generated signal to a tunable input load communica

tively coupled to said LNA.
25. The method according to claim 23, comprising applying said generated signal to a tunable output load communicatively coupled to said LNA.
26. The method according to claim 23, comprising sequen-

tially applying said generated signal to a tunable output load and to a tunable input load communicatively coupled to said LNA.

27. The method according to claim 23, comprising generating a received signal strength indicator (RSSI) signal from an output of said LNA generated after said application of said control signal to said at least one tunable load communica

tively coupled to said LNA.
28. The method according to claim 27, comprising generating said control signal for controlling said at least one tunable load communicatively coupled to said LNA based on said generated RSSI signal.

29. The method according to claim 23, wherein said at least one tunable load communicatively coupled to said LNA is a capacitor bank.

30. A computer readable medium having stored thereon, a computer program having at least one code section for pro cessing signals in a wireless device, the at least one code section being executable by a computer for causing the com puter to perform steps comprising:

generating a signal via an on-chip frequency synthesizer in a multi-band wireless receiver chip; and

dynamically modifying a gain in a low-noise amplifier (LNA) within said multi-band wireless receiver chip for a receiver channel, by applying a control signal based on said generated signal to at least one tunable load com municatively coupled to said LNA.

31. The computer readable medium according to claim 30, wherein said at least one code section comprises code for applying said generated signal to a tunable input load com municatively coupled to said LNA.

32. The computer readable medium according to claim 30, wherein said at least one code section comprises code for applying said generated signal to a tunable output load com municatively coupled to said LNA.

33. The computer readable medium according to claim 30, wherein said at least one code section comprises code for sequentially applying said generated signal to a tunable out put load and to a tunable input load communicatively coupled to said LNA.

34. The computer readable medium according to claim 30, wherein said at least one code section comprises code for generating a received signal strength indicator (RSSI) signal from an output of said LNA generated after said application of said control signal to said at least one tunable load com municatively coupled to said LNA.

35. The computer readable medium according to claim 34, wherein said at least one code section comprises code for generating said control signal for controlling said at least one tunable load communicatively coupled to said LNA based on said generated RSSI signal.

36. The computer readable medium according to claim **30**, wherein said at least one tunable load communicatively coupled to said LNA is a capacitor bank.

37. A system for processing signals in a wireless device, the system comprising:

- a multi-band wireless receiver chip comprising an on-chip frequency synthesizer;
- said frequency synthesizer is operable to generate a signal; and
- said multi-band wireless receiver is operable to dynamically modify a gain in a low-noise amplifier (LNA) within said multi-band wireless receiver chip for a receiver channel, by applying a control signal based on said generated signal to at least one tunable load com municatively coupled to said LNA.

38. The system according to claim 37, comprising one or more circuits that are operable to apply said generated signal to a tunable input load communicatively coupled to said LNA.

39. The system according to claim 37, comprising one or more circuits that are operable to apply said generated signal to a tunable output load communicatively coupled to said LNA.

40. The system according to claim 37, comprising one or more circuits that are operable to sequentially apply said generated signal to a tunable output load and to a tunable input load communicatively coupled to said LNA.

41. The system according to claim 37, comprising one or more circuits that are operable to generate a received signal strength indicator (RSSI) signal from an output of said LNA generated after said application of said control signal to said at least one tunable load communicatively coupled to said **LNA**

42. The system according to claim 41, wherein said one or more circuits within said multi-band wireless receiver chip are operable to generate said control signal for controlling said at least one tunable load communicatively coupled to said LNA based on said generated RSSI signal.
43. The system according to claim 41, wherein said one or

more circuits external to said multi-band wireless receiver chip are operable to generate said control signal for control ling said at least one tunable load communicatively coupled to said LNA based on said generated RSSI signal.

44. The system according to claim 37, wherein said at least one tunable load communicatively coupled to said LNA is a capacitor bank.

45. A method for wireless communication, the method comprising:

- adding a received signal with a reference oscillator signal to generate an added signal;
- generating a mixed signal from said added signal using said reference oscillator signal; and
- tuning a wireless antenna that receives said received signal based on a received signal strength indicator (RSSI) associated with said mixed signal.

46. The method according to claim 45, comprising gener

ating said reference oscillator signal.
47. The method according to claim 46, comprising amplifying said generated reference oscillator signal.

48. The method according to claim 45, comprising ampli fying said added signal prior to said generating of said mixed signal.

49. The method according to claim 45, comprising deter mining said RSSI associated with said mixed signal.

50. The method according to claim 45, wherein said tuning occurs during receiving of a preamble of a packet for said received signal.

51. The method according to claim 45, wherein said tuning occurs during receiving of a plurality of packets for said received signal.

52. The method according to claim 51, comprising switch ing between a plurality of settings for said tuning of said wireless antenna during said receiving of said plurality of packets.

53. The method according to claim 52, wherein each of said plurality of settings corresponds to a respective one of said plurality of packets.

54. The method according to claim 53, comprising deter mining a plurality of RSSI values for each of said plurality of settings based on said respective one of said plurality of packets.

55. The method according to claim 54, comprising tuning said wireless antenna utilizing at least one of said plurality of settings corresponding to a maximum one of said determined plurality of RSSI values.

56. A system for wireless communication, the system com prising:

- at least one circuit, within a receiver comprising a receive
wireless antenna, that enables adding of a received signal with a reference oscillator signal to generate an added signal;
- said at least one circuit enables generation of a mixed signal from said added signal using said reference oscil lator signal; and
- said at least one circuit enables tuning of said receive wireless antenna based on a received signal strength indicator (RSSI) associated with said mixed signal.

57. The system according to claim 56, wherein said at least one circuit enables generation of said reference oscillator signal.

58. The system according to claim 57, wherein said at least one circuit enables amplifying of said generated reference oscillator signal.

59. The system according to claim 56, wherein said at least one circuit enables amplifying of said added signal prior to said generating of said mixed signal.

60. The system according to claim 56, wherein said at least one circuit enables determining of said RSSI associated with said mixed signal.

61. The system according to claim 56, wherein said tuning occurs during receiving of a preamble of a packet for said received signal.

62. The system according to claim 56, wherein said tuning occurs during receiving of a plurality of packets for said received signal.

63. The system according to claim 62, wherein said at least one circuit enables Switching between a plurality of settings for said tuning of said wireless antenna during said receiving of said plurality of packets.

64. The system according to claim 63, wherein each of said plurality of settings corresponds to a respective one of said plurality of packets.

65. The system according to claim 64, wherein said at least one circuit enables determining of a plurality of RSSI values for each of said plurality of settings based on said respective one of said plurality of packets.

66. The system according to claim 65, wherein said at least one circuit enables tuning of said wireless antenna utilizing at least one of said plurality of settings corresponding to a maxi mum one of said determined plurality of RSSI values.
