(57) **ABSTRACT**

Systems and methods for robust, efficient, and secure client-server communication are provided. For example, one method of such client-server communication may involve receiving in the server a long polling HTTP request and a client status message, such as a file offer, via HTTP from the client. Such a file offer may indicate, for example, one or more files that are available for transfer from the client. Thereafter, the server may issue a command, such as a file request, as a response to the long polling HTTP request. Such a file request may request at least one of the one or more files that are available for transfer. There-after, the server may receive the at least one of the one or more files from the client via FTP.

FIG. 1

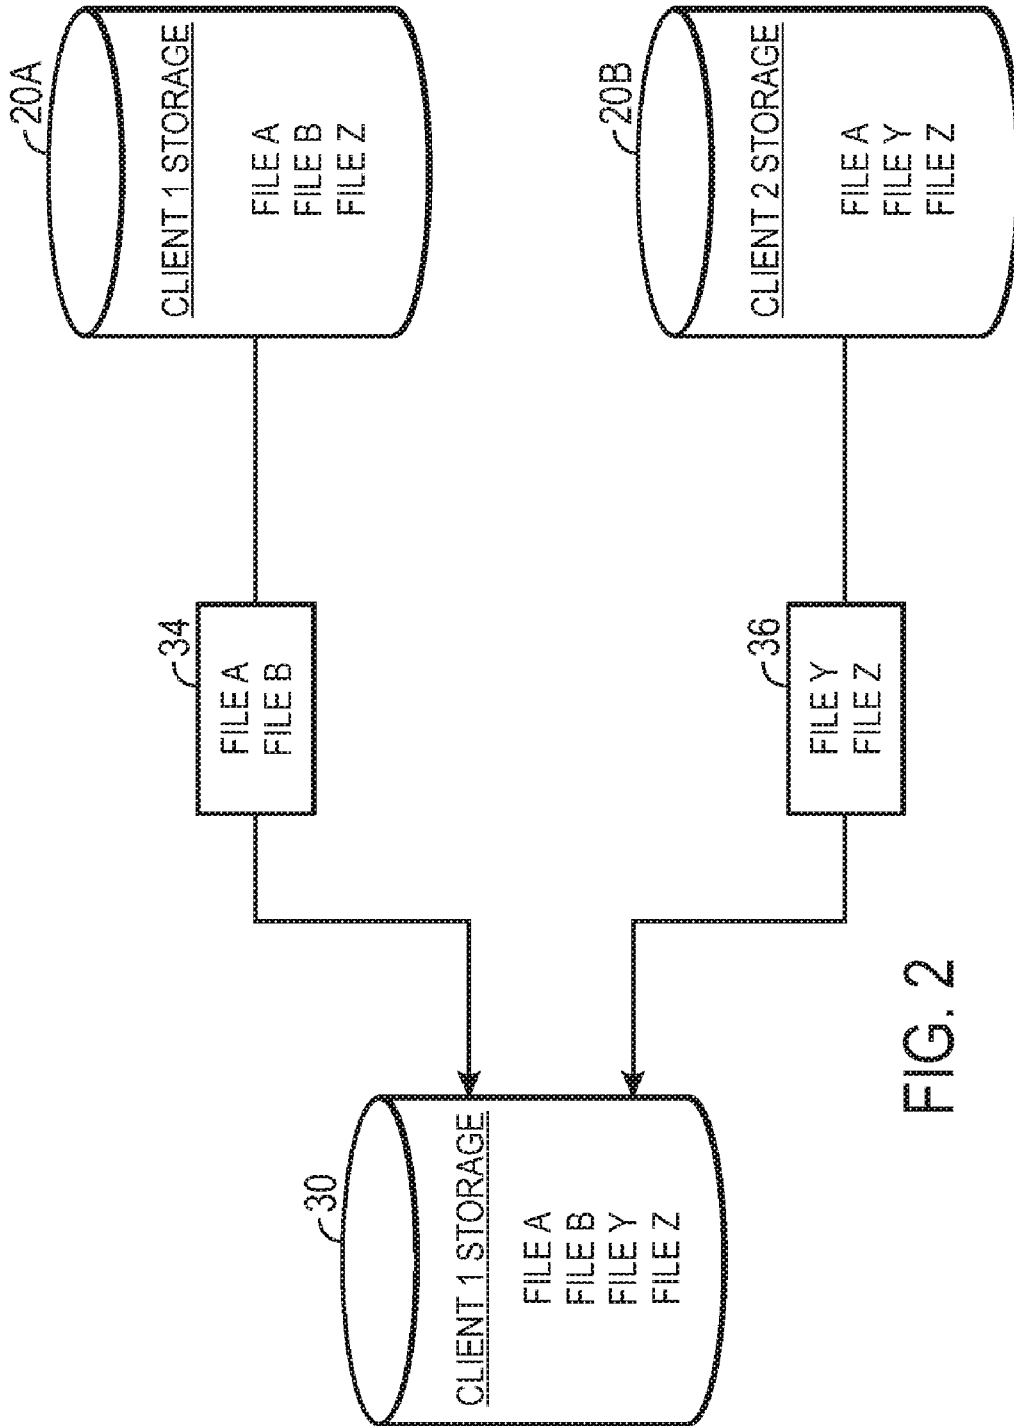

FIG. 2

FIG. 3

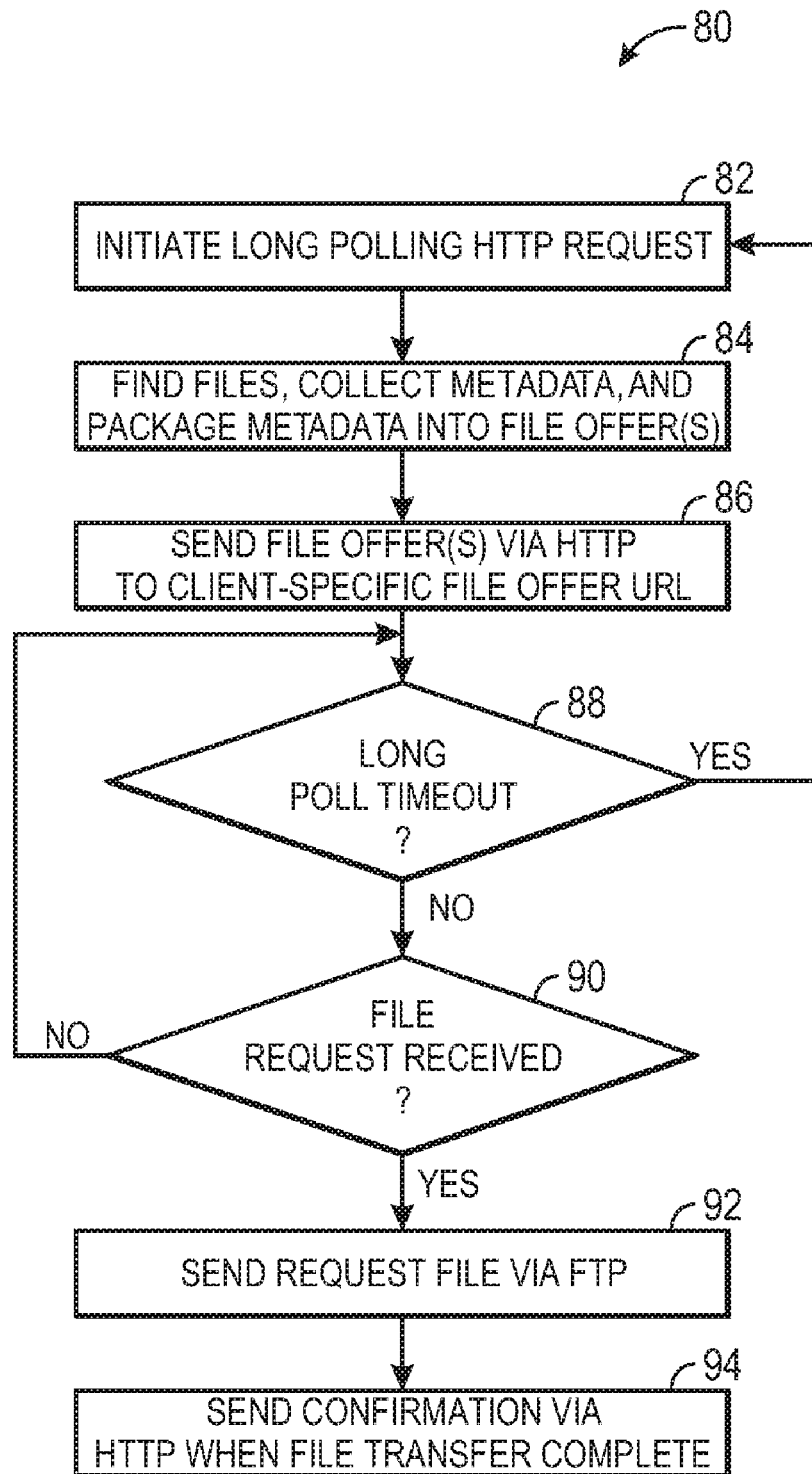

FIG. 4

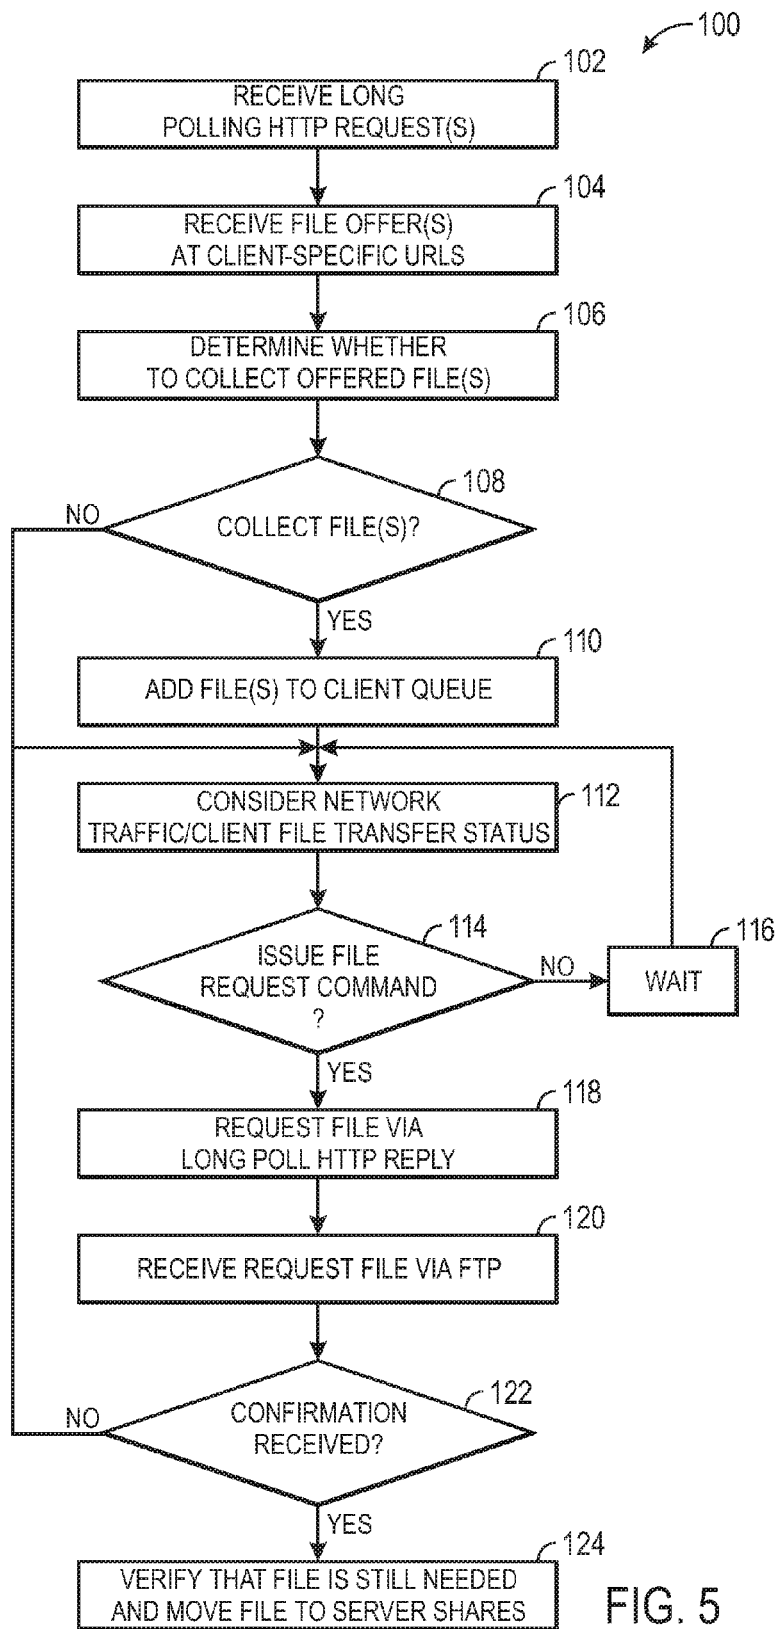

FIG. 5

HTTP-BASED CLIENT-SERVER COMMUNICATION SYSTEM AND METHOD

BACKGROUND

[0001] This section is intended to introduce the reader to various aspects of art, which may be related to various aspects of the present disclosure that are described or claimed below. This discussion is believed to be helpful in providing the reader with background information to facilitate a better understanding of the various aspects of the present disclosure. Accordingly, it should be understood that these statements are to be read in this light, and not as admissions of prior art.

[0002] A user may store a variety of files locally on several different computers, but may desire access to these files from each computer. For example, a user may create or store a variety of media files, such as photos, music, and videos on various home computers belonging to the user. These files may be copied onto a home server, such as a server based on Microsoft Windows Home Server (WHS). The home server may allow the user to stream remote copies of the photos, music, and videos from the server to the various home computers.

[0003] Manually copying files from individual computers to a server may be tedious. Thus, users may desire that a server perform an automatic collection of certain files without significant user intervention. Techniques have been developed to perform such automatic file collection, but these techniques may have certain limitations. For example, these techniques may limit server-initiated communication for access security purposes and/or may inefficiently copy the same files from multiple clients.

BRIEF DESCRIPTION OF THE DRAWINGS

[0004] FIG. 1 is a block diagram of a client-server system, in accordance with an embodiment;

[0005] FIG. 2 is a block diagram describing a manner in which files from the client may be stored on the server, in accordance with an embodiment;

[0006] FIG. 3 is a flow diagram illustrating a manner of automatic file collection, in accordance with an embodiment;

[0007] FIG. 4 is a flowchart describing an embodiment of a method for the client-side of the automatic file collection of FIG. 3; and

[0008] FIG. 5 is a flowchart describing an embodiment of a method for the server-side of the automatic file collection of FIG. 3.

DETAILED DESCRIPTION OF SPECIFIC EMBODIMENTS

[0009] One or more embodiments of the present disclosure will be described below. In an effort to provide a concise description of these embodiments, not all features of an actual implementation are described in the specification. It should be appreciated that in the development of any such actual implementation, as in any engineering or design project, numerous implementation-specific decisions must be made to achieve the developers' specific goals, such as compliance with system-related and business-related constraints, which may vary from one implementation to another. Moreover, it should be appreciated that such a development effort might be complex and time consuming, but would nevertheless be a routine undertaking of design, fabrication, and manufacture for those of ordinary skill having the benefit of this disclosure.

[0010] Present embodiments relate to robust, secure, and efficient HTTP-based client-server communication. According to such embodiments, rather than provide each client direct access to shares of storage on a server and allow each client to save files onto the server shares, each client may transfer files only when requested to do so by the server. In particular, a given client may initiate a long polling Hypertext Transfer Protocol (HTTP) request to the server. The server then may respond to the long polling request with a command to the client when the server is ready. In this way, the server may securely request a specific file from the client without direct access to the client's file system.

[0011] Concurrently, the client may collect information regarding available files in local client storage. The client may transmit this collected file information via a file offer over HTTP to an HTTP handler on the server side, which may respond with an HTTP acknowledgement. It is from such file offers that the server may determine what files are stored on the various clients that are not stored on the server. The server then may request those files from the client by sending a filed request command in response to the long polling HTTP request originally sent by the client. By subsequently transferring the file to the server via file transfer protocol (FTP), the client may provide the file without direct access to the server shares.

[0012] Since the client initiates all communication with the server, a relatively high level of security for the client may be maintained. Moreover, since the server may decide when to issue a file request to the client in response to the long polling HTTP request as needed, the server may request that the client send certain files only when network bandwidth is available. It should also be noted that the present embodiments may be more efficient because the server may select which client supplies a given file when that file is available on multiple clients. By allowing the server to select a single point of origin for the file, the tendency for multiple clients to copy the same file to the server may be reduced or eliminated.

[0013] With the foregoing in mind, FIG. 1 represents such a client-server system 10 that includes one or more clients 12 capable of communicating via HTTP with a server 14. As such, the client-server system 10 may include at least one server 14 and any suitable number of clients 12, labeled in FIG. 1 as 1 to N. Each client 12 may include, among other things, one or more processor(s) 16, memory 18, storage 20, a user interface 22, and a network interface 24. The various functional blocks of the client 12 may include hardware elements, software elements, or a combination of both. The blocks of the client 12 illustrated in FIG. 1 are intended to represent only one example of a particular implementation of the client 12 and are intended to illustrate the types of components that may be present in the client 12.

[0014] By way of example, the client 12 may be a notebook or desktop computer produced by Hewlett-Packard Company. Additionally or alternatively, the client 12 may be any other suitable electronic device capable of storing files and initiating communication with the server 14 via HTTP. The processor(s) 16 and/or other data processing circuitry may be operably coupled to the memory 18 and the storage 20 to perform various algorithms for carry out the presently closed client-server techniques. These algorithms may be encoded in programs and/or instructions that may be executed by the processor(s) 12 and stored in any suitable article of manufacturer that includes one or more tangible, computer-readable

media at least collectively storing the instructions or routines, such as the memory 18 and/or the storage 20.

[0015] The storage 20 may store many files, some of which may be duplicated in the nonvolatile storage 20 of other clients 12. Among other things, the storage 20 of the client 12 may contain media files, such as photos, music, and videos. When a user interacts with the client 12 via the user interface 22 (e.g., a display, speakers, and/or a keyboard and mouse), the user may access or modify the files contained in the storage 20. In some embodiments, the client 12 may stream files from the server 14 or may gain access to files located at the server 14.

[0016] The server 14 may represent any suitable server capable of carrying out the presently disclosed client-server communication. By way of example, the server 14 may be a home server capable of running Microsoft Windows Home Server (WHS), such as the HP MediaSmart Server by Hewlett-Packard Company. Like the client 12, the server 14 may include one or more processor(s) 26, memory 28, non-volatile storage 30, and a network interface 32. These components 26-32 may operate in manner similar to corresponding components of the client 12.

[0017] The server 14 may collect certain files from the storages 20 of clients 12 in communication with the server 14. In particular, as shown in FIG. 2, the server storage 30 generally may include at most one copy of a given file, even though that file may simultaneously be stored at more than one client 12. FIG. 2 illustrates two storages 20A and 20B respectively belonging to two different clients 12 in the client-server system 10. As illustrated, the client storage 20A includes three files labeled "A", "B", and "Z". The client storage 20B includes three files labeled "A", "Y", and "Z". Although six instances of the files are stored on the client storages 20A and 20B, only four unique files exist in total. Thus, to obtain one unique copy of each file, the server storage 30 may only need to receive a few of the files from each of the client storages 20A and 20B. As shown, the server storage 30 may obtain a first set of files 34 (files "A" and "B") from the first client storage 20A and a second set of files 36 (files "Y" and "Z") from the second client storage 20B.

[0018] To collect certain files, the client-server system 10 may perform an automatic file collection technique 40, as shown in FIG. 3. The automatic file collection technique 40 may involve communication between the server 14 and any suitable number of clients 12. As illustrated by FIG. 3, each client 12 participating in the client-server system 10 may operate via two parallel threads, namely, a command/request thread 42 and a file collection thread 44.

[0019] In general, the command/request thread 42 may issue and maintain a long polling HTTP request 46 to a long poll handler 48 of the server 14. The long polling HTTP request 46 may form a first line of communication with the server 14 that the server 14 may respond to at will. The long polling HTTP request 46 may not terminate for an extended period of time, and may be reissued by the command/request thread 42 when the long polling HTTP request 46 times out without a response. When the server 14 elects to issue a command to the client 12, such as a file request 50 or a configuration reload message, the server 14 may issue the command as a response to the long polling HTTP request 46. Because the server 14 is only responding to HTTP communication initiated by the client 12, no special authentication or intrusive interfaces running on the client 12, such as web servers, are needed to send commands from the server 14 to

the client 12. After receiving such a response to the long polling HTTP request 46, the command/request thread 42 may issue and maintain the long polling HTTP request 46 again.

[0020] The file collection thread 44 may determine the status of certain files stored on the storage 20 of the client 12. For example, the file collection thread 44 may find all of certain types of files (e.g., all media files) that are stored in the storage 20 on the client 12. Collecting metadata associated with these files, the file collection thread 44 may package such metadata into one or more file offers 52 that describe what files are available for transfer from the client 12 to the server 14. Subsequently, the file collection thread 44 may transmit the one or more of the file offers 52, via HTTP, to a client-specific uniform resource locator (URL) at the server 14.

[0021] An HTTP handler 54 on the server 14 may receive the file offer 52 from the client 12 and reply with an acknowledgement packet 56. By receiving the acknowledgement packet 56, the file collection thread 44 may know which file offers 52 have been received by the server 14 and which may have been disrupted due to network or other failure. File offers 52 that have been disrupted may be resent at a later time.

[0022] Upon receiving a file offer 52, the server 14 may determine whether the one or more files described in the file offer 52 should be requested from the client 12. For example, if the file offer 52 indicates that the client 12 is storing a file not currently located on the server storage 30, or storing a file that is located in the server storage 30, but has been modified since last being copied, the server 14 may determine to collect the offered file (block 58). A request for this desired file 58 may be added to a client queue 60 on the server 14, which may include a list of files the server 14 should request from the various clients 12. Based on the client queue 60, and depending on the current network traffic and other considerations, as discussed below, the server 14 may decide to request a specific file (block 62) from the client 12.

[0023] The long poll handler 48 may see a specific file request 62 on the client queue 60 and, in response to a long polling HTTP request 46, may reply with a file request 50 command. Such a file request 50 may include certain identifying information that may specifically identify the file requested by the file request 50. The command/request thread 42 of the client 12 may receive the file request 50 command. In response, the command/request thread 42 may transfer a copy of the file 64 via the transfer protocol (FTP) to FTP space 66 on the server 14.

[0024] When the file has been fully transferred, the command/request thread 42 may issue a confirmation message 68 over HTTP to a client-specific the confirmation URL at the server 14. This confirmation message 68 may include the identifying information associated with the file request 50 to indicate that that file has been fully transferred. When the confirmation message 68 is received by the HTTP handler 54, the HTTP handler 54 may verify that the requested file 64, now located in the FTP space 66, is still needed. If so, the HTTP handler 54 may cause the file to be transferred from the FTP space 66 into an appropriate location in the server shares of the storage 30. The HTTP handler 54 also may provide an acknowledgement packet 70 to indicate that it has received the confirmation message 68.

[0025] The particular elements of the technique 40 performed by the client 12 and the server 14 are represented by

FIGS. 4 and 5, respectively. Turning first to FIG. 4, a flowchart 80 represents an embodiment of a method for carrying out the technique 40 from the perspective of the client 12. The flowchart 80 may begin when the command/request thread 42 issues the long polling HTTP request 46 (block 82). Separately, the file collection thread 44 may find certain files, collect metadata regarding these files, and package such metadata into one or more file offers (block 84). It should be appreciated that the file collection thread 44 may perform such a task regardless of whether the client 12 is currently able to connect to the server 14 (e.g., as may occur if a network connection to the server 14 becomes unavailable). In carrying out block 84, the file collection thread 44 may transmit the one or more file offers 52 via HTTP to a client-specific file offer URL at the server 14.

[0026] As noted above, the command/request thread 42 may operate largely independent of the file collection thread 44. In general, the command/request thread 42 may ensure that the long polling HTTP connection remains open to the server 14. To that end, if the long polling HTTP request 46 times out (decision block 88), the command/request thread 42 may issue another long polling HTTP request 46 (block 82). Otherwise, the command/request thread 42 may wait until a command, such as a file request command 50, is received in reply to the long polling HTTP request 46 (decision block 90).

[0027] When a file request 50 is received in response to the long polling HTTP request 46, the command/request thread 42 may obtain and transfer the requested file via FTP to the server 14 (block 92). When the file has been transferred, the command/request thread 42 may send a confirmation message 68 via HTTP (block 94).

[0028] A flowchart 100 of HG. 5 represents the actions taken by the server 14 in carrying out the automatic file collection technique 40. The flowchart 100 may begin when the long poll handler 48 of the server 14 receives one or more long polling HTTP requests 46 from corresponding clients 12 (block 102). As should be appreciated, the long poll handler 48 may not necessarily respond to these long polling HTTP requests 46 immediately. As a result, the various long polling HTTP requests 46 may occasionally timeout and be resent. The long poll handler 48 thus may receive new long polling HTTP requests 46 as they are resent, which may occur at other times throughout the flowchart 100. Moreover, if a long polling HTTP connection breaks (e.g., the server 14 fails to receive a long polling HTTP request 46 from a given client 12), the server 14 may save communication (e.g., file requests 50) for a later time when the long polling HTTP connection becomes available once again.

[0029] At some point, the HTTP handler 54 on the server 14 may receive one or more file offers 52 at certain client-specific uniform resource locators (URLs) (block 104). For example, to revisit the example of FIG. 2, the server 14 may receive file offers 52 indicating that files "A", "B", and "Z" are available for transfer at a first URL associated with a first client 12. Meanwhile, the server 14 may receive file offers 52 indicating that files "A", "Y", and "Z" are available for transfer at a second URL associated with a second client 12. Based on these file offers 52 and/or what files may already be stored in the storage 30 of the server 14, the server 14 may determine whether to collect such files and from which client 12 to do so from (block 106). In one embodiment, if one of the clients 12 is likely to transfer the files more efficiently or for other reasons, file transfers from that client 12 may be prioritized.

[0030] If the server 14 determines to collect a given file indicated by a file offer 52 (decision block 108), a request for the specific file may be added to a client queue 60 (block 110), before considering certain factors relating to the status of the network and/or the clients 12 (block 112). Otherwise, if the server 14 determines not to collect a given file from a file offer 52 (decision block 108), the process may flow directly to block 112 without adding any new file requests to the client queue 60. The various factors considered at block 112 may include, for example, the current amount of traffic over the network, whether a client 12 is currently transferring a file to the server 14, whether the server 14 is currently streaming a file (e.g., a music or video file) to a client 12, and/or whether a client 12 is currently actively performing a task that a file request 50 would interfere with.

[0031] Based on the status of the network and/or the status of a client 12, the server 14 may decide to issue a file request command 50 to the client 12 for a file listed for request in the client queue 60. If the server 14 determines not to issue the file request command 50 based on the current network status and/or client 12 status (decision block 114), the server 14 may wait for a certain period of time (block 116) before again reconsidering the factors to decide whether to issue the file request command 50. If the server 14 determines to issue a file request command 50 based on favorable network status and/or client 12 status (decision block 114), the long poll handler 48 may respond to the open long polling HTTP request 46 of the client 12 from which the file is requested (block 118).

[0032] The server 14 then may receive the requested file from the client 12 via FTP (block 120). If the server 14 fails to receive a confirmation message 68 (decision block 122), the server 14 may elect to reissue the file request command 50 again at another time. For example, the server 14 may periodically check (e.g., once a day, once every hour, once every half hour, and so forth) whether a confirmation message 68 has been received for a requested file. In some embodiments, the server 14 may check whether a confirmation message 68 has been received after a certain expected amount of data has been received, based on an expected size of a requested file.

[0033] When a confirmation message 68 is received by the HTTP handler 54 (decision block 122), the server 14 may verify that the received file is still needed before moving the file from the FTP space 66 to the server shares of the storage 30. For example, in some embodiments, the confirmation message 68 may include metadata associated with the file that has been transferred. The server 14 may use the metadata associated with the recently received file to determine whether the file transferred is up-to-date. That is, if the file had changed since the receipt of the file request 50, as may have been indicated by a new file offer 52, the server 14 may determine that the recently transferred file is not needed. In this way, the server 14 may ensure that the files contained on its storage 30 are up-to-date, particularly in case communication between the client 12 and server 14 is disrupted.

[0034] It should be noted that the client-server system 10 may be more secure than other similar systems because, according to the automatic file collection technique 40, the client 12 initiates all communication with the server 14. In particular, the server 14 may send commands on demand in response to the long polling HTTP request 46, which may be continually refreshed by the client 12. As mentioned above, sending commands in response to the long polling HTTP request 46 may eliminate a need for intrusive access to the client 12 by the server 14 and vice versa. For example, the

client-server system **10** may not require special authentication or intrusive interfaces running on the client **12**, such as web servers, to perform automatic file collection. Also, the client **12** may elect not to receive commands from the server **14** by allowing the long polling HTTP request **46** to timeout without reissuing another long polling HTTP request **46**.

[0035] Additionally, the client-server system **10** may be more system-focused rather than user-focused. That is, under the automatic file collection technique **40**, the server **14**, rather than the clients **12**, decides whether to transfer a given file to the server storage **30**. Because the server **14** may receive file offers **52** from many clients **12**, the server **14** may consider both the files that are currently stored in the server storage **30** and the files are available for offer from the individual clients **30**. The server **14** thus may gain a system-wide view of files available for transfer, files that have already been transferred, and files that are scheduled to be transferred in the future.

[0036] This system-wide view may increase efficiency. For example, the server **14** may leverage its system-wide knowledge to handle file collisions (e.g., when two copies of the same file or similar files are stored locally different clients **12**), which might otherwise lead to multiple copies of the same file being stored on the storage **30** of the server **14**. Moreover, the server **14** may throttle file transfers based on the status of the network and the statuses of individual clients **12** to maintain a desired level of performance.

[0037] Finally, the automatic file collection technique **40** may not only increase efficiency, but also may prove more robust. Specifically, the client **12** may be aware of communication failures with the server **14** and the server **14** may be aware of communication failures with each client **12**. As noted above, if the client **12** sends a file offer **52**, but does not receive an HTTP acknowledgment **56**, the client **12** may queue the file offer **52** for transmittal at another time. If the client **12** transfers a file via FTP to the server **14** and subsequently sends a confirmation message **68** to the server **14**, the client **12** may queue the file for re-transmittal if no HTTP acknowledgment **70** is received in response. Similarly, if the server **14** issues a command, such as a file request **50**, but never receives a confirmation message, the server **14** may queue and resend the command again at a later time. In addition, if the server **14** should fail for any reason, the state of its client queue **60** may be saved. Thus, while certain file transfer progress may be lost, file requests **50** may simply be re-transmitted when the client **12** and the server **14** regain communication.

[0038] In addition, it should be understood that the automatic file collection technique **40** may be extended for many other forms of client-server communication. For example, in response to the long polling HTTP request **46**, the server **14** may provide any suitable command alternatively to or in addition to a file request **52**. Such a command may enable the server **14** to initiate, for example, a backup procedure on the client **12** or a configuration status reload procedure. Thus, for example, upon receipt of such a command, the command/request thread **42** may cause another thread, such as the file collection thread **44**, to resend all file offers **52**. In another example, in response to the command, the command/request thread **42** may cause another thread to initiate a backup procedure. Other commands the server **14** may send in response to the long polling HTTP request **46** may include, for example, an indication of what space has been allocated on the server storage **30**.

[0039] The specific embodiments described above have been shown by way of example, and it should be understood that these embodiments may be susceptible to various modifications and alternative forms. It should be further understood that the claims are not intended to be limited to the particular forms disclosed, but rather to cover all modifications, equivalents, and alternatives falling within the spirit and scope of this disclosure.

What is claimed is:

1. A method comprising:

receiving, in a server, a long polling HTTP request from a client;

receiving, in the server, a file offer from the client via HTTP, wherein the file offer indicates one or more files that are available for transfer from the client;

issuing, from the server, a file request in response to the long polling HTTP request, wherein the file request requests at least one of the one or more files that are available for transfer; and

receiving, in the server, the at least one of the one or more files from the client via FTP.

2. The method of claim 1, wherein the file offer is received at a client-specific uniform resource locator (URL) that identifies the client.

3. The method of claim 1, comprising receiving, in the server, a confirmation message indicating that the at least one of the one or more files has been fully transferred at a client-specific uniform resource locator (URL) that identifies the client.

4. The method of claim 1, comprising determining, using the server, whether a confirmation message indicating that the at least one of the one or more files has been fully transferred has been received in the server from the client and, when the confirmation has been received, storing the at least one of the one or more files in the server.

5. The method of claim 1, comprising determining, using the server, whether a confirmation message indicating that the at least one of the one or more files has been transferred has been received in the server from the client and, when the confirmation has not been received, reissuing the file request from the server.

6. The method of claim 5, wherein determining whether the confirmation message has been received from the client is performed on a periodic basis.

7. The method of claim 5, wherein determining whether the confirmation message has been received from the client is performed after an amount of data has been received from the client, wherein the amount of data is estimated to equal a size of the at least one of the one or more files.

8. The method of claim 1, comprising determining, using the server, whether the one or more files that are available for transfer from the client should be requested and, when the one or more files are determined to be requested, adding the file request for the one or more files to a client queue that lists files for which future file requests are to be issued, wherein the file request is issued based at least in part on the client queue.

9. The method of claim 1, comprising determining, using the server, that network traffic or traffic to the client is beneath a threshold before issuing the file request.

10. The method of claim 1, comprising determining, using the server, that the client is not receiving a streamed file before issuing the file request.

11. A system comprising:

a client configured to initiate a long polling HTTP request, to communicate information regarding the client to a client-specific uniform resource locator via HTTP, and to receive a client-specific command in response to the long polling HTTP request; and

a server configured to receive the long polling HTTP request, to receive the information regarding the client at a client-specific uniform resource locator via HTTP, to generate the client-specific command based at least in part on the information regarding the client, and to communicate the client-specific command as a response to the long polling HTTP request.

12. The system of claim **11**, wherein the information regarding the client comprises a file offer indicating one or more files available for transfer from the client and wherein the command comprises a file request that requests at least one of the one or more files.

13. The system of claim **11**, comprising another client configured to initiate another long polling HTTP request, to communicate information regarding the other client to another client-specific uniform resource locator via HTTP, and to receive another client-specific command in response to the other long polling HTTP request;

wherein the server is configured to receive the other long polling HTTP request, to receive the information regarding the other client at the other client-specific uniform resource locator via HTTP, to generate the other client-specific command based at least in part on the information regarding the client, and to communicate the other client-specific command as a response to the long polling HTTP request.

14. A method comprising:

initiating a long polling HTTP request from a client to a server;

transmitting a file offer via HTTP from the client to the server, wherein the file offer indicates one or more files that are available for transfer from the client to the server;

receiving, in the client, a file request from the server in response to the long polling HTTP request, wherein the file request requests at least one of the one or more files that are available for transfer; and

transferring the at least one of the one or more files from the client to the server via FTP.

15. The method of claim **14**, comprising determining, using the client, the file offer by collecting and packaging metadata associated with the one or more files that are available for transfer.
