(57) **ABSTRACT**

A gripping apparatus includes: a temperature adjusting device held in a substrate wherein the substrate defines an open region; a phase change material held within the open region and thermally coupled with the temperature adjusting device such that a temperature change in the temperature adjusting device causes a temperature change in the phase change material; and a controller connected to the temperature adjusting device and configured to send a signal to the temperature adjusting device to change its temperature and thereby change the temperature of the phase change material that is thermally coupled with the temperature adjusting device. The phase change material is either in a solid state and configured to grip a stick or in a liquid state and the phase change material and configured to loosen its grip on the stick such that the stick is capable of moving through the phase change material.

POSITIONING APPARATUS AND GRIPPING APPARATUS

CROSS REFERENCE TO RELATED APPLICATION

This application is a divisional of U.S. application Ser. No. 16/538,281, filed on Aug. 12, 2019 and titled POSITIONING APPARATUS AND GRIPPING APPARATUS, which claims the benefit of U.S. Application No. 62/718,251, filed Aug. 13, 2018 and titled POSITIONING APPARATUS AND GRIPPING APPARATUS. Both of these applications are incorporated herein by reference in their entirety.

TECHNICAL FIELD

This disclosure relates to a gripping apparatus configured to control a grip on and a motion of a stick and a positioning apparatus in which the gripping apparatus can be used.

BACKGROUND

Probes can be used to research animal tissue, for example, for neurophysiological research or for clinical diagnostic uses in animals. For example, a movable single channel or single electrode mechanism can record from a single location (such as a visual cortex) in the brain of an animal.

SUMMARY

In some general aspects, a gripping apparatus includes: a temperature adjusting device held in a substrate wherein the substrate defines an open region; a phase change material held within the open region and thermally coupled with the temperature adjusting device such that a temperature change in the temperature adjusting device causes a temperature change in the phase change material; and a controller connected to the temperature adjusting device and configured to send a signal to the temperature adjusting device to change its temperature and thereby change the temperature of the phase change material that is thermally coupled with the temperature adjusting device. When the phase change material is at a temperature below a first transition temperature, the phase change material is in a solid state and the phase change material is configured to grip a stick within the phase change material. When the phase change material is at a temperature above a second transition temperature, the phase change material is in a liquid state and the phase change material is configured to loosen its grip on the stick such that the stick is capable of moving through the phase change material.

Implementations can include one or more of the following features. For example, the stick can extend through the phase change material.

The phase change material can include one or more of: wax; paraffin wax; and alkane hydrocarbon. The alkane hydrocarbon can include one or more of: n-octacosane, n-heptacosane, n-hexacosane, n-pentacosane, n-tetracosane, n-docosane, n-tricosane, n-heneicosane, n-eicosane, n-nonadecane, n-octadecane, n-heptadecane, n-hexadecane, n-pentadecane, n-tetradecane, and n-tridecane. The phase change material can be selected so that the transition between the solid state and the liquid state at the first or second transition temperature occurs at an operating temperature for the gripping apparatus.

2

The stick can be rigid enough to withstand motion through the phase change material without fracturing or bending or kinking.

The first transition temperature and the second transition temperature can be at room temperature, at a temperature of a living organism, at a temperature below room temperature, or at a temperature above room temperature.

The stick can include one or more of: at least one conductor; at least one measurement probe; at least one capillary tube; at least one optical waveguide; and at least one carbon fiber; and at least one sonic waveguide. The at least one measurement probe can include an electrical testing probe, a silicon probe, an electrical recording probe, or an ultrasonic probe.

The substrate can generally be defined in an x-y plane, and when the phase change material can be at a temperature above the second transition temperature, the stick being capable of moving through the phase change material along a z axis that is perpendicular to the x-y plane.

A cross section of the stick taken along a plane can be a circular shape, a polygonal shape, or an irregular asymmetric shape.

The temperature adjusting device can include a resistive conductive wire and the controller can include a power source that supplies a current to the resistive conductive wire, wherein the resistive conductive wire changes its temperature as the current is changed. The temperature adjusting device can include one or more of: a resistive material deposited in the open region of the substrate; a chip resistor adjacent to the open region of the substrate; a wire-wound resistor in the open region of the substrate; and a carbon paste coated in the open region of the substrate.

The substrate can include a printed circuit board.

The phase change material can be held within the open region by way of capillary forces. The phase change material can remain within the open region even if it is in the liquid state.

The first transition temperature can be equal to the second transition temperature.

In other general aspects, a positioning apparatus includes: an actuator drive movable along an axial direction; a first gripping apparatus fixed to the actuator drive, the first gripping apparatus including a first phase change material that is configured to receive a first region of a stick; a second gripping apparatus fixed to the actuator drive, the second gripping apparatus including a second phase change material that is aligned along an axial direction with the first phase change material and that is configured to receive a second region of the stick; and a controller connected to the first gripping apparatus, the second gripping apparatus, and to the actuator drive. The controller is configured to provide one or more signals to the actuator drive, the first gripping apparatus, and the second gripping apparatus. The one or more signals provided to the first gripping apparatus control a phase of the first phase change material and the one or more signals provided to the second gripping apparatus control a phase of the second phase change material. A position of the stick along the axial direction is adjusted or held constant depending on the one or more signals provided to the actuator drive, the first gripping apparatus, and the second gripping apparatus.

Implementations can include one or more of the following features. For example, the actuator drive can have a first end and a second end. The first and second ends can be movable relative to each other. The first gripping apparatus can be

fixed to the first end of the actuator drive. The second gripping apparatus can be fixed to the second end of the actuator drive.

The actuator drive can include one or more of: a turnable screw configured to turn about the axial direction to thereby translate the second end relative to the first end along the axial direction; a stepper motor configured to move the second end relative to the first end along the axial direction; a shape memory alloy configured to expand or contract to thereby adjust a relative position between the first end and the second end; and a piezoelectric actuator configured to move the second end relative to the first end along the axial direction.

The first end of the actuator drive can be fixed and the second end of the actuator drive can be movable relative to the first end of the actuator drive.

The actuator drive can be movable along only the axial direction under control of the controller. The first gripping apparatus can further include: a first temperature adjusting device held in a first rigid substrate, the first rigid substrate defining a first open region and being fixed to the actuator drive to thereby fix the first gripping apparatus to the actuator drive. The first phase change material can be held within the first open region and can be thermally coupled with the first temperature adjusting device such that a temperature change in the first temperature adjusting device causes a temperature change in the first phase change material. The controller can be connected to the first temperature adjusting device of the first gripping apparatus such that the provision of the signal to the first gripping apparatus controls a temperature of the first temperature adjusting device to thereby control a temperature of the first phase change material. The second gripping apparatus can further include: a second temperature adjusting device held in a second rigid substrate, the second rigid substrate defining a second open region and being fixed to the actuator drive to thereby fix the second gripping apparatus to the actuator drive. The second phase change material can be held within the second open region and can be thermally coupled with the second temperature adjusting device such that a temperature change in the second temperature adjusting device causes a temperature change in the second phase change material. The controller can be connected to the second temperature adjusting device of the second gripping apparatus such that the provision of the signal to the second gripping apparatus controls a temperature of the second temperature adjusting device to thereby control a temperature of the second phase change material.

The controller can include: a first control module connected to the first gripping apparatus; a second control module connected to the second gripping apparatus; and an actuator module connected to the actuator drive. The first control module can control a phase of the first phase change material, the first phase change material being either in a solid phase state in which the first phase change material grips the stick or a liquid phase state in which the first phase change material loosens its grip on the stick such that the stick is capable of moving through the first phase change material along the axial direction. The second control module can control a phase of the second phase change material, wherein the second phase change material is either in a solid phase state in which the second phase change material grips the stick or a liquid phase state in which the second phase change material loosens its grip on the stick such that the stick is capable of moving through the second phase change material along the axial direction. The actuator module can

control the relative position between a first end of the actuator drive and a second end of the actuator drive along the axial direction.

The actuator module can provide a temporally-varying signal to the actuator drive; and a position of the stick along the axial direction can be adjusted by adjusting the one or more signals provided to the first gripping apparatus and to the second gripping apparatus. The position of the stick along the axial direction can be adjusted without adjusting a signal provided to the actuator drive.

The controller can further include a master control module connected to the first control module, the second control module, and the actuator module. The master control module can control the signals provided to each of the first control module, the second control module, and the actuator module.

The second gripping apparatus can be thermally independent of the first gripping apparatus.

In other general aspects, a positioning apparatus includes: a single actuator drive movable along an axial direction; a plurality of axial holders, each axial holder configured to receive a stick and each axial holder being fixed to the single actuator drive; and a controller in communication with the single actuator drive and with the plurality of axial holders. The controller is configured to: provide an actuation signal to the single actuator drive; and provide at least one independent signal to each of the axial holders. The position of each stick is independently adjustable along the axial direction by the adjustment of the provided at least one independent signal to each of the axial holders without adjusting the provided actuation signal to the single actuator drive.

Implementations can include one or more of the following features. The single actuator drive can include a first end and a second end; and the first and second ends can be movable relative to each other along the axial direction. Each axial holder can include a first gripping apparatus fixed to the first end of the single actuator drive and a second gripping apparatus fixed to the second end of the single actuator drive. The second gripping apparatus can be aligned along an axial direction with the first gripping apparatus. For each axial holder: the first gripping apparatus can be configured to receive a first region of the stick that is received in that axial holder and the second gripping apparatus can be configured to receive a second region of the stick that is received in that axial holder. For each axial holder: the first gripping apparatus can include a phase change material that is configured to receive the first region of the stick that is received in that axial holder; and the second gripping apparatus can include a phase change material that is configured to receive the second region of the stick that is received in that axial holder.

The actuation signal can be provided to the single actuator drive by providing a temporally-varying signal to the single actuator drive, the temporally-varying signal controlling an axial position associated with the single actuator drive.

Each axial holder can be configured to interact with at least two interaction regions of its associated stick. At each interaction region, the stick can be received in a gripping apparatus. At least one independent signal can be provided to each of the axial holders by providing an independent signal to each gripping apparatus in each axial holder. Each gripping apparatus can include a temperature adjusting device; and a phase change material thermally coupled with the temperature adjusting device such that a temperature change in the temperature adjusting device causes a temperature change in the phase change material. The independent signal can be provided to a gripping apparatus by

providing an independent signal to the temperature adjusting device, and the state of the phase change material can be selected by adjustment of the provided independent signal to the temperature adjusting device thermally coupled with the phase change material.

In other general aspects, a method includes: providing a single actuation signal to a single actuator drive, wherein the single actuation signal controls a movement of the single actuator drive along an axial direction; providing an independent signal to each axial holder of a plurality of axial holders, wherein each axial holder receives a stick and each axial holder is fixed to the single actuator drive; and independently adjusting a position of a stick along the axial direction by adjusting the provided independent signal to the axial holder that receives that stick and without adjusting the provided actuation signal to the single actuator drive.

Implementations can include one or more of the following features. For example, the single actuation signal can be provided to the single actuator drive by controlling a relative movement between a first end of the single actuator drive and a second end of the single actuator drive along the axial direction. The single actuation signal can be provided to the single actuator drive by providing a temporally-varying signal to the single actuator drive, the temporally-varying signal controlling an axial position associated with the single actuator drive.

An independent signal can be provided to an axial holder by providing an independent signal to a gripping apparatus in that axial holder. The independent signal can be provided to a gripping apparatus by providing an independent signal to a temperature adjusting device of the gripping apparatus. The method can further include selecting a state of a phase change material thermally coupled to the temperature adjusting device by adjusting the provided independent signal to the temperature adjusting device thermally coupled with that phase change material.

In some general aspects, a method includes providing a single actuation signal to a single actuator drive, wherein the single actuation signal controls a movement of the single actuator drive along an axial direction; providing an independent signal to each axial holder of a plurality of axial holders, wherein each axial holder receives a stick and each axial holder is fixed to the single actuator drive; and independently adjusting a position of a stick along the axial direction by adjusting the provided independent signal to the axial holder that receives that stick and without adjusting the provided actuation signal to the single actuator drive.

The single actuation signal can be provided to the single actuator drive by controlling a relative movement between a first end of the single actuator drive and a second end of the single actuator drive along the axial direction. The single actuation signal can be provided to the single actuator drive by providing a temporally-varying signal to the single actuator drive, the temporally-varying signal controlling an axial position associated with the single actuator drive.

An independent signal can be provided to an axial holder by providing an independent signal to a gripping apparatus of that axial holder. The independent signal can be provided to a gripping apparatus by providing an independent signal to a temperature adjusting device of the gripping apparatus. Moreover, the method can include selecting a state of a phase change material thermally coupled to the temperature adjusting device by adjusting the provided independent signal to the temperature adjusting device thermally coupled with that phase change material.

DESCRIPTION OF DRAWINGS

FIG. 1 is a schematic perspective view of a gripping apparatus configured to control a grip on and a motion of a stick;

FIG. 2A is a side cross-sectional view of an implementation of the gripping apparatus of FIG. 1, in which the stick is gripped;

FIG. 2B is a top cross-sectional view of the implementation of the gripping apparatus of FIG. 1, in which the stick is gripped;

FIG. 3A is a side cross-sectional view of an implementation of the gripping apparatus of FIG. 1, in which the stick is released;

FIG. 3B is a top cross-sectional view of the implementation of the gripping apparatus of FIG. 1, in which the stick is released;

FIG. 4A is a side cross-sectional view and FIG. 4B is a top cross-sectional view of an implementation of a temperature adjusting device of a gripping apparatus;

FIG. 5A is a side cross-sectional view and FIG. 5B is a top cross-sectional view of an implementation of a temperature adjusting device of a gripping apparatus;

FIG. 6A is a side cross-sectional view and FIG. 6B is a top cross-sectional view of an implementation of a temperature adjusting device of a gripping apparatus;

FIGS. 7A-7E show side cross-sectional view of an implementation of steps of a procedure for manufacturing a gripping apparatus such as the gripping apparatus of FIG. 1;

FIG. 8 is a schematic perspective view of a positioning apparatus including the gripping apparatus of FIG. 1 and configured to control a grip on and a motion of a stick;

FIG. 9 is a block diagram of an implementation of a controller of the positioning apparatus of FIG. 8;

FIG. 10A shows side cross-sectional views of the positioning apparatus of FIG. 8 at distinct times in an exemplary signal cycle during which aspects of the positioning apparatus are adjusted to thereby affect a movement of a stick along a $-z$ direction of a z axis;

FIG. 10B shows a timing diagram of three signal amplitudes versus time that correlates with each of the times depicted in FIG. 10A;

FIG. 11A shows side cross-sectional views of the positioning apparatus of FIG. 8 at distinct times in an exemplary signal cycle during which aspects of the positioning apparatus are adjusted to thereby affect a movement of a stick along a $+z$ direction of a z axis;

FIG. 11B shows a timing diagram of three signal amplitudes versus time that correlates with each of the times depicted in FIG. 11A;

FIG. 12A shows side cross-sectional views of the positioning apparatus of FIG. 8 at distinct times in an exemplary signal cycle during which aspects of the positioning apparatus are adjusted but a stick remains stationary;

FIG. 12B shows a timing diagram of three signal amplitudes versus time that correlates with each of the times depicted in FIG. 12A;

FIG. 13 is a block diagram of an implementation of a positioning apparatus designed to independently translate each of a plurality of sticks along an axial direction of that stick using an actuator drive;

FIG. 14 is a perspective view of an implementation of the positioning apparatus of FIG. 13;

FIG. 15 is a partial side cross-sectional view of the implementation of the positioning apparatus of FIG. 14;

FIGS. 16A-16E a block diagrams, each showing an implementation of a configuration of sticks in the positioning apparatus of FIG. 13;

FIGS. 17A-17D show top plan views of an implementation of a positioning apparatus such as the positioning apparatus shown in FIGS. 13-15, with steps in manufacturing depicted;

FIGS. 18A, 18B, and 18D show perspective views of an implementation of a positioning apparatus such as the positioning apparatus of FIGS. 13-15;

FIGS. 18C and 18E show an implementation of the sticks of the positioning apparatus of FIGS. 13-15;

FIG. 19A shows a schematic representation of an implementation of a positioning apparatus of FIGS. 13-15; and

FIG. 19B shows a close-up view of an area of a substrate of the positioning apparatus of FIG. 19A in which each temperature adjusting device is a chip resistor.

DETAILED DESCRIPTION

Referring to FIG. 1, a gripping apparatus 100 is designed to control a grip on and also a motion of a stick 105. The sizes and geometry of features and elements in FIG. 1 are exaggerated to show details. The stick 105 can be any structure, device, or apparatus that generally extends along an axial direction 110. The stick 105 can be a solid structure or a hollow structure or a more complex structure made up of more than one material or region. In some implementations, the stick 105 can be used to measure one or more properties of some other element. In other implementations, the stick 105 can be used as an actuator to effect or modify one or more characteristics of another element. For example, the stick 105 can include an electrical conductor (such as a cable or wire); a measurement probe; a capillary tube; an optical waveguide; an optical fiber; a carbon fiber or filament; or a sonic waveguide. If the stick 105 is a measurement probe, then it could include an electrical testing probe, a silicon probe, an electrical recording probe, or an ultrasonic probe.

The stick 105 can be made of any material that is capable of withstanding motion without fracturing or bending or kinking. Thus, the stick 105 has a level of rigidity that enables it to be gripped as well as released and moved. A cross section of the stick 105 taken along a plane that is perpendicular to the axial direction 110 can have any geometric shape and it may or may not have symmetry. For example, the cross section can be a circular shape, a polygonal shape, an oval shape, or an irregular asymmetric shape.

The gripping apparatus 100 includes a temperature adjusting device 115 held or fixed in a substrate 120, and a phase change material 125. The substrate 120 defines an open region 122 that is large enough to accommodate the phase change material 125 as well as the stick 105 and any other components that may be used during assembly or manufacturing. The phase change material 125 is thermally coupled to the temperature adjusting device 115. This means that a temperature change in the temperature adjusting device 115 causes a temperature change in the phase change material 125. The stick 105 extends through the phase change material 125.

The gripping apparatus 100 also includes a controller 130. The controller 130 is connected to the temperature adjusting device 115 and is configured to send a signal to the temperature adjusting device 115 to change its temperature. The change in temperature affected at the temperature adjusting device 115 causes the temperature of the phase change

material 125 that is thermally coupled with the temperature adjusting device 115 to change as well.

The phase change material 125 is a material that is able to transition between two distinct phases of matter as a result of a change in temperature. For example, the phase change material 125 can transition between a solid state and a liquid state. In some implementations, the phase change material 125 includes wax; paraffin wax; or alkane hydrocarbon. The alkane hydrocarbon can be any one or more of: n-octacosane, n-heptacosane, n-hexacosane, n-pentacosane, n-tetracosane, n-docosane, n-tricosane, n-heneicosane, n-eicosane, n-nonadecane, n-octadecane, n-heptadecane, n-hexadecane, n-pentadecane, n-tetradecane, and n-tridecane.

When in a liquid state, the phase change material 125 is held within the open region 122 by way of capillary action (and without the assistance of or in opposition to other external forces such as gravity). This happens because the adhesive forces, that is, the intermolecular attractive forces between the phase change material 125 and the solid surrounding surface of one or more of the temperature adjusting device 115 and the substrate 120, are stronger than the cohesive forces within the phase change material 125. If the size of the open region 122 (for example, a diameter taken in the plane perpendicular to the axial direction 110) is sufficiently small, then the combination of surface tension (which is caused by cohesion within the liquid) and adhesive forces act together to keep the phase change material 125 in the open region 122. In this way, the phase change material 125 remains within the open region 122 even if it is in the liquid state. The amount of phase change material 125 that is held within the open region 122 can be adjusted during assembly so that any expansion of the phase change material 125 during changes in phase is maintained within the open region 122. Thus, even if the phase change material 125 expands with a change in temperature, it can still remain contained in the open region 122. Additionally, in some implementations, the material of the phase change material 125 is not chemically reactive or attracted to the material of the stick 105.

The substrate 120 is generally defined in a plane that is perpendicular to the axial direction 110. For example, if the axial direction 110 is defined as the z axis, then the substrate 120 extends along the x-y plane. The substrate 120 also has a thickness along the z axis. In some implementations, the substrate 120 includes a printed circuit board. In such implementations, as discussed below, the communication channel (which can be an electrical connection) between the temperature adjusting device 115 and the controller 130 can be formed in the printed circuit board.

The controller 130 can include one or more of digital electronic circuitry, computer hardware, firmware, software, and a power supply. The controller 130 includes memory, which can be read-only memory and/or random-access memory. Storage devices suitable for tangibly embodying computer program instructions and data include all forms of non-volatile memory, including, by way of example, semiconductor memory devices, such as EPROM, EEPROM, and flash memory devices; magnetic disks such as internal hard disks and removable disks; magneto-optical disks; and CD-ROM disks. The controller 130 can also include one or more input devices (such as a keyboard, touch screen, microphone, mouse, hand-held input device, etc.) and one or more output devices (such as a speaker or a monitor).

The controller 130 includes one or more programmable processors, and one or more computer program products tangibly embodied in a machine-readable storage device for

execution by a programmable processor. The one or more programmable processors can each execute a program of instructions to perform desired functions by operating on input data and generating appropriate output. Generally, the processor receives instructions and data from memory. Any of the foregoing may be supplemented by, or incorporated in, specially designed ASICs (application-specific integrated circuits). The controller 130 includes at least one module that includes a set of computer program products executed by one or more processors such as the processors. Moreover, the module can access data stored within the memory. The module can be in communication with a dedicated other component of the gripping apparatus 100 (for example, the temperature adjusting device 115).

Although the controller 130 is represented as a box (in which all of its components can be co-located), it is possible for the controller 130 to be made up of components that are physically remote from each other. In general, the controller 130 can perform functions not discussed herein.

The change of phase in the phase change material 125 is discussed with reference to FIGS. 2A-3B. In FIGS. 2A and 2B, the stick 105 is gripped, which means that it is fixed relative to the gripping apparatus 100 and is therefore prevented from moving relative to the gripping apparatus 100. By contrast, in FIGS. 3A and 3B, the stick 105 is released, which means that the stick 105 is capable of moving relative to the gripping apparatus 100. For example, the stick 105 is capable of moving along the axial direction 110.

When the phase change material 125 is at a temperature below a first transition temperature T1 (FIGS. 2A and 2B), the phase change material 125 is in a solid state. In this state, the phase change material 125 grips the stick 105 that is within the phase change material 125. The first transition temperature T1 is defined as that temperature at which the phase change material 125 is fully in the solid state after previously being in the liquid state.

When the phase change material 125 is at a temperature above a second transition temperature T2 (FIGS. 3A and 3B), the phase change material 125 is in a liquid state. In this state, the phase change material 125 loosens its grip on the stick 105 such that the stick 105 is capable of moving through the phase change material 125. The second transition temperature T2 is defined as that temperature at which the phase change material 125 is fully in the liquid state after previously being in the solid state.

Moreover, the transition between the solid state and the liquid state at the first transition temperature T1 or the second transition temperature T2 occurs at an operating temperature suitable for the gripping apparatus 100.

When the phase change material 125 is at a temperature above the second transition temperature T2, the stick 105 is capable of moving through the phase change material 125 along the z axis that is perpendicular to the x-y plane.

In some implementations, depending on the application of the stick 105, the first transition temperature T1 and the second transition temperature T2 can be at or near room temperature (for example, 20-25° C.). In other implementations, the first transition temperature T1 and the second transition temperature T2 can be at or near a temperature of a living organism (for example, 36-43° C.). In other implementations, the first transition temperature T1 and the second transition temperature T2 can be below room temperature, or above room temperature.

The first transition temperature T1 can be equal to the second transition temperature T2. However, because of hysteresis, it is possible and likely that the transition tem-

peratures T1 and T2 are not equal. The actual transition temperatures T1 and T2 depends on the previous state of the gripping apparatus 100. For example, the first transition temperature T1 is less than the second transition temperature T2. Additionally, as discussed above, the first transition temperature T1 is defined as that temperature at which the phase change material 125 is fully in the solid state after previously being in the liquid state. It is possible that the phase change material 125 remains in a fully solid state at a temperature above the first transition temperature T1 if the phase change material 125 is transitioning from a fully solid state to a liquid state. Similarly, it is possible that the phase change material 125 remains in a fully liquid state at a temperature below the second transition temperature T2 if the phase change material 125 is transitioning from a fully liquid state to a solid state.

Additionally, there may exist intermediate phases within the range of temperatures between the first transition temperature T1 and the second transition temperature T2 for some phase change materials 125.

The temperature adjusting device 115 is a device that is configured to change its temperature and enable heat transfer between the temperature adjusting device 115 and the phase change material 125. Moreover, the temperature adjusting device 115 is configured to be held in place in the substrate 120. In some implementations, the temperature of the temperature adjusting device 115 is modified or changed by a change in current that is applied to the temperature adjusting device 115. Thus, the temperature adjusting device 115 can include an element that is able to conduct current but has a high enough resistance to enable its temperature to change by a suitable amount with a change in current.

Referring to FIGS. 4A-6B, various implementations of the temperature adjusting device 115 are shown that are based on this resistive temperature control. The stick 105 is not shown in FIGS. 4A-6B but would be placed in and received in the open region 122.

In FIGS. 4A and 4B, the temperature adjusting device 115 is a resistive material 415 that is formed in or deposited in the open region 122. The resistive material 415 can be any metal that is conductive and has enough resistance to enable temperature adjustment. The resistive material 415 is formed so that it bonds to the interior surface of the substrate 120 that defines the open region 122. In some implementations, the resistive material 415 can be a carbon paste that coats the interior surface of the substrate 120 that defines the open region 122.

In FIGS. 5A and 5B, the temperature adjusting device 115 is a chip resistor 515 embedded within the open region 122 that receives the phase change material 125. In this way, the chip resistor 515 is in thermal communication with the phase change material 125.

In FIGS. 6A and 6B, the temperature adjusting device 115 is a resistive conductive wire 615 that is wound into a spiral shape inside the open region 122 of the substrate 120. The wire 615 can be made of a metal alloy such as nichrome, which is an alloy of nickel and chrome.

In these implementations, the controller 130 includes a power source that supplies a current to the resistive element (such as the resistive material 415, the chip resistor 515, or the conductive wire 615) by way of electrically conductive elements 116, 117 (such as contacts or leads).

Referring to FIGS. 7A-7E, the gripping apparatus 100 is formed as follows. As shown in FIG. 7A, the substrate 120 is selected. As discussed above, the substrate 120 can be a blank region of a printed circuit board, and the printed circuit board can include other structures or regions not

shown in FIGS. 7A-7E. Moreover, while not shown in FIGS. 7A-7E, it is possible for these other structures or regions of the printed circuit board to have different or specialized thermal properties. As shown in FIG. 7B, the open region 122 is formed in the substrate 120. The open region 122 can be formed by drilling a hole into the substrate 120 or using a milling machine or any suitable device for removing the material of the substrate 120. As shown in FIG. 7C, the temperature adjusting device 115 is formed so that it is held or fixed in the substrate 120. For example, the temperature adjusting device 115 can be held or fixed in the substrate 120 by gluing, epoxy, or embedding. The temperature adjusting device 115 can be formed in the open region 122 or adjacent to the open region 122, as long as it is located to be in thermal communication with the phase change material 125. If the temperature adjusting device 115 is the resistive conductive wire 615, then it can be wound inside the open region 122 touching the substrate 120. If the temperature adjusting device 115 is the resistive material 415 then it can be painted on, deposited on, plated on, or soldered into the open region 122, touching the substrate 120. If the temperature adjusting device 115 is the chip resistor 515, then it can be snapped or embedded into an opening such as the open region 122 and fixed into place by connection with the conductive elements 116, 117.

As shown in FIG. 7D, the phase change material 125 is deposited in the open region 122 so that it is in thermal communication with the temperature adjusting device 115. One way to deposit the phase change material 125 is to melt the phase change material 125 so that it is in a liquid state. The liquid form of the phase change material 125 can be drawn up or into the open region 122 using capillary forces or action in a wicking process. Once the phase change material 125 is fully deposited into the open region 122, as while the phase change material 125 is still in its liquid state, the stick 105 is inserted into the phase change material 125 and electrical connections are made between the temperature adjusting device 115 and the controller 130.

The gripping apparatus 100 can be formed in a manner that is different from that described with reference to FIGS. 7A-7E. For example, in other implementations, the phase change material 125 is added after the stick 105 is inserted into or through the open region 122.

Referring to FIG. 8, the gripping apparatus 100 can be used in a positioning apparatus 840 that is designed to move a stick 805 along an axial direction 810, which is parallel with the z axis. The stick 805 is shown for reference in FIG. 8 but is not necessarily a part of the positioning apparatus 840. The positioning apparatus 840 includes an actuator drive 842 movable along the axial direction 810. In some implementations, the actuator drive 842 can move along only the axial direction 810.

The positioning apparatus 840 includes a first gripping apparatus 800A fixed to the actuator drive 842, a second gripping apparatus 800B fixed to the actuator drive 842, and a controller 845. The controller 845 is in communication with the first gripping apparatus 800A, the second gripping apparatus 800B, and the actuator drive 842 and thus the controller 845 controls the operation of each of the first gripping apparatus 800A, the second gripping apparatus 800B, and the actuator drive 842. Communication between the controller 845 and other elements of the positioning apparatus 840 can be wired or wireless.

The first and second gripping apparatuses 800A, 800B are designed like the gripping apparatus 100. Thus, the first gripping apparatus 800A includes a first phase change material 825A that is configured to receive a first region

805_1 of the stick 805. And, the second gripping apparatus 800B includes a second phase change material 825B that is aligned along the axial direction 810 with the first phase change material 825A and that is configured to receive a second region 805_2 of the stick 805.

The controller 845 is configured to provide one or more signals to the actuator drive 842, the first gripping apparatus 800A, and the second gripping apparatus 800B. In order to facilitate communications, the positioning apparatus 840 can include a sub-controller 830A in communication with the first gripping apparatus 800A, a sub-controller 830B in communication with the second gripping apparatus 800B, and a sub-controller 831 in communication with the actuator drive 842. Any communication between the controller 845 and the actuator drive 842 is conveyed by the sub-controller 831; any communication between the controller 845 and the first gripping apparatus 800A is conveyed by the sub-controller 830A; and any communication between the controller 845 and the second gripping apparatus 800B is conveyed by the sub-controller 830B.

The one or more signals provided to the first gripping apparatus 800A control a phase of the first phase change material 825A, and the one or more signals provided to the second gripping apparatus 800B control a phase of the second phase change material 825B. In this way, a position of the stick 805 along the axial direction 810 is adjusted or held constant depending on the one or more signals provided to the actuator drive 842, the first gripping apparatus 800A, and the second gripping apparatus 800B, as discussed in greater detail below. The controller 845 can be configured to adjust or control a timing and synchronization between the changes in the actuator drive 842 and the changes in the first and second phase change materials 825A, 825B.

The actuator drive 842 has a first end 842_1 and a second end 842_2. The first end 842_1 and the second end 842_2 are movable relative to each other. Thus, for example, the second end 842_2 can move while the first end 842_1 remains stationary in the x, y, z coordinate system, the first end 842_1 can move while the second end 842_2 remains stationary in the x, y, z coordinate system, or both the first end 842_1 and the second end 842_2 can move in the x, y, z coordinate system. If the first gripping apparatus 800A is fixed to the first end 842_1 of the actuator drive 842 and the second gripping apparatus 800B is fixed to the second end 842_2 of the actuator drive 842, then the relative movement between the first and second gripping apparatuses 800A, 800B can be controlled.

The actuator drive 842 can be any suitable drive that permits a relative motion between the first end 842_1 and the second end 842_2. Thus, the actuator drive 842 can be configured to perform one or more of the following controls: moving both the first end 842_1 and the second end 842_2 relative to each other; moving the first end 842_1 and maintaining the second end 842_2 stationary; and maintaining the first end 842_1 stationary and moving the second end 842_2.

In some implementations, the actuator drive 842 is a turnable screw configured to turn about the axial direction 810 to thereby translate the second end 842_2 relative to the first end 842_1 along the axial direction 810. In other implementations, the actuator drive 842 is a stepper motor configured to move the second end 842_2 relative to the first end 842_1 along the axial direction 810.

In other implementations, the actuator drive 842 is a piezoelectric actuator configured to move the second end 842_2 relative to the first end 842_1 along the axial direction 810. The voltage level applied to the piezoelectric material

in the actuator is adjusted to thereby adjust a relative displacement between the first end **842_1** and the second end **842_2**.

In still other implementations, the actuator drive **842** includes a shape memory alloy that is configured to expand when heated, which causes the second end **842_2** and the first end **842_1** to move farther apart, and to contract when cooled, which causes the second end **842_2** and the first end **842_1** to move closer together. An example of a shape memory alloy is nitinol, which is an alloy of nickel and titanium.

As mentioned, the first gripping apparatus **800A** and the second gripping apparatus **800B** can be designed like the gripping apparatus **100**. Thus, the first gripping apparatus **800A** includes a first temperature adjusting device **815A** held in a first rigid substrate **820A**. The first rigid substrate **820A** defining a first open region that receives the first temperature adjusting device **815A**. The first rigid substrate **820A** is fixed to the actuator drive **842** to thereby fix the first gripping apparatus **800A** to the actuator drive **842**. The first phase change material **825A** is held within the first open region and is thermally coupled with the first temperature adjusting device **815A** such that a temperature change in the first temperature adjusting device **815A** (which is affected under control of the controller **845**) causes a temperature change in the first phase change material **825A**. The controller **845** is in communication with the first temperature adjusting device **815A** of the first gripping apparatus **800A** such that the provision of the signal to the first gripping apparatus **800A** from the sub-controller **830A** controls the temperature of the first temperature adjusting device **815A** to thereby control a temperature of the first phase change material **825A**.

The second gripping apparatus **800B** further includes a second temperature adjusting device **815B** held in a second rigid substrate **820B**, the second rigid substrate defining a second open region and being fixed to the actuator drive **842** to thereby fix the second gripping apparatus **800B** to the actuator drive **842**. The second phase change material **825B** is held within the second open region and is thermally coupled with the second temperature adjusting device **815B** such that a temperature change in the second temperature adjusting device **815B** causes a temperature change in the second phase change material **825B**. The controller **845** is in communication with the second temperature adjusting device **815B** of the second gripping apparatus **800B** such that the provision of the signal to the second gripping apparatus **800B** from the sub-controller **830B** controls the temperature of the second temperature adjusting device **815B** to thereby control a temperature of the second phase change material **825B**.

Referring also to FIG. 9, in some implementations, the controller **845** includes a first control module **946** in communication with the first gripping apparatus **800A** by way of the sub-controller **830A**, a second control module **947** in communication with the second gripping apparatus **800B** by way of the sub-controller **830B**, and an actuator module **948** in communication with the actuator drive **842** by way of the sub-controller **831**. The controller **845** can also include a master module **949** that is in communication with one or more of the first control module **946**, the second control module **947**, and the actuator module **948**.

In general, the controller **845** includes one or more of digital electronic circuitry, computer hardware, firmware, and software. The controller **845** includes memory **950**, which can be read-only memory and/or random-access memory. Storage devices suitable for tangibly embodying

computer program instructions and data include all forms of non-volatile memory, including, by way of example, semiconductor memory devices, such as EPROM, EEPROM, and flash memory devices; magnetic disks such as internal hard disks and removable disks; magneto-optical disks; and CD-ROM disks. The controller **845** can also include one or more input devices (such as a keyboard, touch screen, microphone, mouse, hand-held input device, etc.) and one or more output devices (such as a speaker or a monitor) **951**.

The controller **845** includes one or more programmable processors **952**, and one or more computer program products tangibly embodied in a machine-readable storage device for execution by a programmable processor. The one or more programmable processors can each execute a program of instructions to perform desired functions by operating on input data and generating appropriate output. Generally, the processor receives instructions and data from memory. Any of the foregoing may be supplemented by, or incorporated in, specially designed ASICs (application-specific integrated circuits).

Each module **946**, **947**, **948**, **949** includes a set of computer program products executed by one or more processors such as the processors **952**. Moreover, any of the modules **946**, **947**, **948**, **949** can access data stored within the memory **950**. Each module **946**, **947**, **948**, **949** can be in communication with one or more other modules **946**, **947**, **948**, **949**.

Although the controller **845** is represented as a box (in which all of its components can be co-located), it is possible for the controller **845** to be made up of components that are physically remote from each other. For example, the first control module **946** can be physically co-located with the first gripping apparatus **800A** or the sub-controller **830A**.

The first control module **946** controls a phase of the first phase change material **825A**. In particular, the first phase change material **825A** is either in a solid phase state in which the first phase change material **825A** grips the stick **805** or a liquid phase state in which the first phase change material **825A** loosens its grip on the stick **805** such that the stick is capable of moving through the first phase change material **825A** along the axial direction **810**. Additionally, the second control module **947** controls a phase of the second phase change material **825B**. The second phase change material **825B** is either in a solid phase state in which the second phase change material **825B** grips the stick **805** or a liquid phase state in which the second phase change material **825B** loosens its grip on the stick **805** such that the stick **805** is capable of moving through the second phase change material **825B** along the axial direction **810**. The actuator module **948** controls the relative position between the first end **842_1** of the actuator drive **842** and a second end **842_2** of the actuator drive **842** along the axial direction **810**.

The controller **845** can provide a temporally-varying signal to the actuator drive **842**. For example, the actuator module **948**, by way of the sub-controller **831**, can provide the temporally-varying signal to the actuator drive **842**. The temporally-varying signal can be a repeatable or somewhat repeatable signal, such as a periodic or pseudo-periodic signal or it can be an irregularly-shaped, yet changing signal that goes through steps to effect changes to the first and second gripping apparatuses **800A**, **800B**. It is not necessary for the periodic or pseudo-periodic signal to have a constant frequency. That is, the frequency with which certain aspects of the signal repeat can change or can include multiple frequencies. Moreover, it is possible for the signal to change its amplitude from each full cycle to the next full cycle.

A position of the stick **805** along the axial direction **810** is adjusted by adjusting the one or more signals provided

from the first control module 946 to the first gripping apparatus 800A and from the second control module 947 to the second gripping apparatus 800B. Moreover, the position of the stick 805 along the axial direction 810 is adjusted without adjusting a signal provided from the actuator module 948 to the actuator drive 842.

The master control module 949 controls the signals provided to each of the first control module 946, the second control module 947, and the actuator module 948.

In other implementations, it is possible for the controller 845 to include fewer modules than what is described and shown in FIG. 9, or that one or more of the modules described and shown in FIG. 9 are combined into a single module or eliminated altogether.

The positioning apparatus 840 is configured to move the stick 805 along the axial direction 810. FIGS. 10A and 10B show an implementation of how the stick 805 is moved along the $-z$ direction. FIGS. 11A and 11B show an implementation of how the stick 805 is moved along the $+z$ direction. FIGS. 12A and 12B show an implementation of how the stick 805 remains stationary along the z axis even though the temporally-varying signal provided from the actuator module 948 to the actuator drive 842 is uninterrupted (and not halted). Each of these implementations are discussed next.

With reference to FIG. 10A, a side cross-sectional view of the positioning apparatus 840 is shown at eight distinct times [(i), (ii), (iii), (iv), (v), (vi), (vii), (viii)] in a signal cycle in order to affect the movement or translation of the stick 805 along the $-z$ direction. FIG. 10B is a timing diagram showing the corresponding three signal amplitudes versus time (in arbitrary units). The top signal is a signal 1033A provided by the sub-controller 830A to the first temperature adjusting device 815A of the first gripping apparatus 800A. The signal 1033A provided to the first temperature adjusting device 815A controls a temperature of the first temperature adjusting device 815A, which therefore controls the temperature and a phase of the first phase change material 825A. The bottom signal is a signal 1033B provided by the sub-controller 830B to the second temperature adjusting device 815B of the second gripping apparatus 800B. The signal 1033B provided to the second temperature adjusting device 815B controls a temperature of the second temperature adjusting device 815B, which therefore controls the temperature and a phase of the second phase change material 825B. And, the middle signal is a signal provided by the sub-controller 831 to the actuator drive 842.

Initially, before time (i), the state of the positioning apparatus 840 is as follows. The signal 1033A is at an OFF amplitude or level, which means that the first temperature adjusting device 815A is below a first temperature and the first phase change material 825A is at a temperature TA that is below the first transition temperature T1. Thus, the first phase change material 825A of the first gripping apparatus 800A is in a solid state, and the first phase change material 825A grips the stick 805 at the first region 805_1. The signal 1033B is at an OFF amplitude or level, which means that the second temperature adjusting device 815B is below a first temperature and the second phase change material 825B is at a temperature TB that is below the first transition temperature T1. Thus, the second phase change material 825B of the second gripping apparatus 800B is in a solid state, and the second phase change material 825B grips the stick 805 at the second region 805_2. The stick 805 is fixed relative to the z axis. Additionally, the signal 1032 is at a LOW amplitude or level, and the voltage applied to the actuator drive 842 is at the LOW amplitude, which means that the

actuator drive 842 is in a contracted state. An amplitude that is LOW can be a low non-zero value or can be zero or off.

At time (i) (FIG. 10B), the signal 1033A has been changed to an ON amplitude or level and the signal 1033B is at an OFF amplitude or level. Additionally, the signal 1032 is at a LOW amplitude or level, and the voltage applied to the actuator drive 842 is at the LOW amplitude, which means that the actuator drive 842 is in a contracted state.

After a period of time from time (i), at time (ii), the first temperature adjusting device 815A is above a second temperature and the first phase change material 825A reaches a temperature TA that is above the second transition temperature T2. Thus, the first phase change material 825A of the first gripping apparatus 800A is in a liquid state (depicted by the dotted fill in FIG. 10A(ii)), and the first phase change material 825A loosens its grip on the stick 805 at the first region 805_1. The signal 1033B remains at an OFF amplitude or level, which means that the temperature adjusting device 815B is below a first temperature and the second phase change material 825B is at a temperature TB that is below the first transition temperature T1. Thus, the second phase change material 825B of the second gripping apparatus 800B is in a solid state (depicted by a grid fill in FIG. 10A(ii)), and the second phase change material 825B grips the stick 805 at the second region 805_2. Additionally, the signal 1032 is still at a LOW amplitude or level, and the voltage applied to the actuator drive 842 is at the LOW amplitude, which means that the actuator drive 842 is in a contracted state. Because of this, even though the grip on the stick 805 is loosened at the first region 805_1, the stick 805 remains fixed relative to the z axis because the stick 805 is still gripped at the second region 805_2.

At time (iii), the signal 1033A remains at the ON amplitude, which means that the first phase change material 825A is at the temperature TA that is above the second transition temperature T2, and the first phase change material 825A of the first gripping apparatus 800A remains in the liquid state. Thus, the first phase change material 825A has a loosened grip on the first region 805_1 of the stick 805. The signal 1033B remains at an OFF amplitude, which means that the second phase change material 825B is at a temperature TB that is below the first transition temperature T1, and the second phase change material 825B of the second gripping apparatus 800B is in a solid state. Thus, the second phase change material 825B grips the second region 805_2 of the stick 805. Now, though, the signal 1032 transitions to a HIGH amplitude or level, and the voltage applied to the actuator drive 842 is at the HIGH amplitude, which means that the actuator drive 842 moves to an expanded state. In the expanded state, in this implementation, the second end 842_2 of the actuator drive 842 is moved along the $-z$ direction relative to the first end 842_1 of the actuator drive 842. Because the second gripping apparatus 800B is fixed to the second end 842_2 of the actuator drive 842 at time (iii) and the grip on the stick 805 is loosened at the first region 805_1, the stick 805 is translated along the $-z$ direction by an amount that corresponds to how much the second end 842_2 of the actuator drive 842 is moved.

At time (iv), the signal 1033A has been switched to an OFF amplitude for some time, and the first phase change material 825A reaches the temperature TA that is below the first transition temperature T1, and the first phase change material 825A of the first gripping apparatus 800A returns to the solid state, as depicted by the grid fill shown in FIG. 10A(iv). Thus, the first phase change material 825A grips the first region 805_1 of the stick 805. The signal 1033B remains at an OFF amplitude, which means that the second

phase change material **825B** is at a temperature **TB** that is below the first transition temperature **T1**, and the second phase change material **825B** of the second gripping apparatus **800B** is in a solid state. Thus, the second phase change material **825B** maintains its grip on the second region **805_2** of the stick **805**. The signal **1032** remains at a HIGH amplitude or level, and the voltage applied to the actuator drive **842** is at the HIGH amplitude, which means that the actuator drive **842** remains in the expanded state. Because the stick **805** is gripped at both the first and second regions **805_1**, **805_2**, the stick **805** remains stationary at this time relative to the **z** axis.

At time (v), the signal **1033A** remains at the OFF amplitude, which means that the first phase change material **825A** is at the temperature **TA** that is below the first transition temperature **T1**, and the first phase change material **825A** of the first gripping apparatus **800A** returns to the solid state. Thus, the first phase change material **825A** grips the first region **805_1** of the stick **805**. The signal **1033B** is changed to an ON amplitude or level. And, the signal **1032** remains at a HIGH amplitude or level, and the voltage applied to the actuator drive **842** is at the HIGH amplitude, which means that the actuator drive **842** remains in the expanded state.

Eventually, after a period of time from time (v), such as at time (vi), the second phase change material **825B** reaches a temperature **TB** that is above the second transition temperature **T2**, and the second phase change material **825B** of the second gripping apparatus **800B** is in a liquid state, as shown by the dotted fill in FIG. **10A**(vi). Thus, the second phase change material **825B** loosens its grip on the second region **805_2** of the stick **805**. The signal **1032** remains at a HIGH amplitude or level, and the voltage applied to the actuator drive **842** is at the HIGH amplitude, which means that the actuator drive **842** remains in the expanded state. The stick **805** remains stationary at this time relative to the **z** axis even though the grip on the stick **805** is loosened at the second region **805_2** because the stick **805** is gripped at the first region **805_1**.

At time (vii), the signal **1033A** remains at the OFF amplitude, which means that the first phase change material **825A** is at the temperature **TA** that is below the first transition temperature **T1**, and the first phase change material **825A** of the first gripping apparatus **800A** is in the solid state. Thus, the first phase change material **825A** grips the first region **805_1** of the stick **805**. The signal **1033B** remains at the ON amplitude, which means that the second phase change material **825B** is at a temperature **TB** that is above the second transition temperature **T2**, and the second phase change material **825B** of the second gripping apparatus **800B** is in a liquid state. Thus, the second phase change material **825B** remains in a state in which its grip on the second region **805_2** of the stick **805** is loosened. The signal **1032** changes from the HIGH amplitude to the LOW amplitude, and the voltage applied to the actuator drive **842** switches to the LOW amplitude, which means that the actuator drive **842** changes to the contracted state. The stick **805** remains stationary at this time because the stick **805** is gripped at the first region **805_1**, which is fixed to the first gripping apparatus **800A**, which is not moving, and although the second gripping apparatus **800B** is moving along the +**z** direction, the stick **805** does not move along because the second region **805_2** of the stick is not gripped by the second gripping apparatus **800B**.

At time (viii), the signal **1033A** remains at the OFF amplitude, which means that the first phase change material **825A** is at the temperature **TA** that is below the first transition temperature **T1**, and the first phase change mate-

rial **825A** of the first gripping apparatus **800A** is in the solid state. Thus, the first phase change material **825A** grips the first region **805_1** of the stick **805**. The signal **1033B** was switched to the OFF amplitude after time (viii) and before time (viii), and eventually, at time (viii), the second phase change material **825B** reaches a temperature **TB** that is below the first transition temperature **T1**, and the second phase change material **825B** of the second gripping apparatus **800B** is in the solid state, as depicted by the grid fill in FIG. **10A**(viii). Thus, the second phase change material **825B** has switched to the state in which it grips the second region **805_2** of the stick **805**. The signal **1032** remains at the LOW amplitude, which means that the actuator drive **842** is in the contracted state. The stick **805** remains stationary at this time because the stick **805** is gripped at the first region **805_1** and at the second region **805_2**.

The ON amplitude of the signal **1033A** and **1033B** as well as the time during which the signal **1033A**, **1033B** remains at the ON amplitude, and the ON voltage of the signal **1032** and the time during which the signal **1032** is at the ON voltage depend on factors such as the resistance, size, and materials of the phase change materials **825A**, **825B** and initial temperatures of various components of the first and second gripping apparatuses **800A**, **800B**.

In some implementations, the ON amplitude of the signal **1033A** or **1033B** can correspond to about tens or hundreds (for example, 10-200) milliamperes (mA) while the ON voltage of the signal **1032** supplied to the actuator drive **842** can be on the order of several tens or hundreds (for example, 10-200) volts (V). The time during which the signal **1033A** or **1033B** remains with an ON amplitude can be on the order of several, tens, or hundreds of (for example, 1-1000) milliseconds (ms) while the time during which the signal **1032** is at the ON voltage (and the actuator drive **842** is in the expanded state) can be on the order of a second or several seconds (for example, 0.1-10 s).

Moreover, it is possible that a temperature and an environment of the first gripping apparatus **800A** is different from a temperature and an environment of the second gripping apparatus **800B** during operation of the positioning apparatus **840**, depending on the application and use of the positioning apparatus **840**. For example, the second gripping apparatus **800B** may be positioned closer to or in contact with a warm-bodied animal, which can raise the temperature of the second gripping apparatus **800B** relative to the first gripping apparatus **800A** (which would be farther from the warm-bodied animal).

It should also be noted that because of this, the first and second transition temperatures **T1** and **T2** of the first phase change material **825A** may be distinct from the first and second transition temperatures **T1** and **T2** of the second phase change material **825B**. For simplicity in description of FIGS. **10A**, **10B**, **11A**, **11B**, **12A**, and **12B**, it is assumed that when referencing the first and second transition temperatures **T1** and **T2**, these are the values specific to the phase change material **825A** or **825B** being described.

With reference to FIG. **11A**, a side cross-sectional view of the positioning apparatus **840** is shown at eight distinct times [(i), (ii), (iii), (iv), (v), (vi), (vii), (viii)] in a signal cycle in order to affect the movement or translation of the stick **805** along the +**z** direction. FIG. **11B** is a timing diagram showing the corresponding three signal amplitudes (**1033A**, **1033B**, and **1032**) versus time (in arbitrary units).

Initially, before time (i), the state of the positioning apparatus **840** is as follows. The signal **1033A** is at an OFF amplitude or level, and thus the first phase change material **825A** of the first gripping apparatus **800A** is in a solid state,

and the first phase change material **825A** grips the stick **805** at the first region **805_1**. The signal **1033B** is at an OFF amplitude or level, and thus the second phase change material **825B** of the second gripping apparatus **800B** is in a solid state, and the second phase change material **825B** grips the stick **805** at the second region **805_2**. The stick **805** is fixed relative to the z axis. Additionally, the signal **1032** is at a LOW amplitude or level, and the voltage applied to the actuator drive **842** is at the LOW amplitude, which means that the actuator drive **842** is in a contracted state.

At time (i), the signal **1033A** remains at an OFF amplitude or level, which means that the first temperature adjusting device **815A** is below a first temperature and the first phase change material **825A** is at a temperature TB that is below the first transition temperature T1. Thus, the first phase change material **825A** of the first gripping apparatus **800A** is in a solid state, and the first phase change material **825A** grips the stick **805** at the first region **805_1**. The signal **1033B** is changed to an ON amplitude or level. Additionally, the signal **1032** is at a LOW amplitude or level, and the voltage applied to the actuator drive **842** is at the LOW amplitude, which means that the actuator drive **842** is in a contracted state.

After a period of time beyond time (i), at time (ii), the second temperature adjusting device **815B** reaches a second temperature and the second phase change material **825B** is at a temperature TB that is above the second transition temperature T2. Thus, the second phase change material **825B** of the second gripping apparatus **800B** reaches a liquid state, as shown by the dotted fill in FIG. 11A(ii), and the second phase change material **825B** loosens its grip on the stick **805** at the second region **805_2**. At time (ii), the signal **1033A** remains at an OFF amplitude or level, thus, the first temperature adjusting device **815A** is below a first temperature and the first phase change material **825A** is at a temperature TB that is below the first transition temperature T1. Thus, the first phase change material **825A** of the first gripping apparatus **800A** is in a solid state, as shown by the grid fill in FIG. 11A(ii), and the first phase change material **825A** grips the stick **805** at the first region **805_1**. Additionally, the signal **1032** is at a LOW amplitude or level, and the voltage applied to the actuator drive **842** is at the LOW amplitude, which means that the actuator drive **842** is in a contracted state. Even though the grip on the stick **805** is loosened at the second region **805_2**, the stick **805** remains fixed relative to the z axis because the stick **805** is still gripped at the first region **805_1**.

At time (iii), the signal **1033A** remains at the OFF amplitude, which means that the first phase change material **825A** is at a temperature TA that is below the first transition temperature T1, and the first phase change material **825A** is in a solid state, as depicted by the grid fill in FIG. 11A(iii). Thus, the first phase change material **825A** maintains its grip on the first region **805_1** of the stick **805**. The signal **1033B** remains at the ON amplitude, which means that the second phase change material **825B** is at the temperature TB that is above the second transition temperature T2, and the second phase change material **825B** of the second gripping apparatus **800B** remains in the liquid state, as depicted by the dotted fill in FIG. 11A(iii). Thus, the second phase change material **825B** maintains its loosened grip on the second region **805_2** of the stick **805**. Now, though, the signal **1032** to the actuator drive **842** transitions to a HIGH amplitude or level, and the voltage applied to the actuator drive **842** is at the HIGH amplitude, which means that the actuator drive **842** moves to an expanded state. In the expanded state, in this implementation, the second end **842_2** of the actuator

drive **842** is moved along the $-z$ direction relative to the first end **842_1** of the actuator drive **842**. Even though the second gripping apparatus **800B** is fixed to the second end **842_2** of the actuator drive **842** at time (iii), because the grip on the stick **805** is loosened at the second region **805_2**, the stick **805** does not translate along the $-z$ direction with the second end **842_2** of the actuator drive **842**.

At time (iv), the signal **1033A** remains at an OFF amplitude, which means that the first phase change material **825A** is at a temperature TA that is below the first transition temperature T1, and the first phase change material **825A** is in a solid state, as depicted by the grid fill in FIG. 11A(iv). Thus, the first phase change material **825A** maintains its grip on the first region **805_1** of the stick **805**. The signal **1033B** was switched to an OFF amplitude before time (iv), and by the time (iv), the second phase change material **825B** reaches the temperature TB that is below the first transition temperature T1, and the second phase change material **825B** of the second gripping apparatus **800B** returns to the solid state, as depicted by the grid fill in FIG. 11A(iv). Thus, the second phase change material **825B** grips the second region **805_2** of the stick **805**. The signal **1032** remains at a HIGH amplitude or level, and the voltage applied to the actuator drive **842** is at the HIGH amplitude, which means that the actuator drive **842** remains in the expanded state. Because the stick **805** is gripped at both the first and second regions **805_1**, **805_2**, the stick **805** remains stationary at this time relative to the z axis.

At time (v), the signal **1033A** has been changed to an ON amplitude or level, and the signal **1033B** remains at the OFF amplitude, which means that the second phase change material **825B** is at the temperature TB that is below the first transition temperature T1, and the second phase change material **825B** of the second gripping apparatus **800B** remains in the solid state and grips the second region **805_2** of the stick **805**. Moreover, the signal **1032** remains at a HIGH amplitude or level, and the voltage applied to the actuator drive **842** is at the HIGH amplitude, which means that the actuator drive **842** remains in the expanded state.

After a period of time from time (v), at time (vi), the first phase change material **825A** reaches a temperature TA that is above the second transition temperature T2, and the first phase change material **825A** is in a liquid state, as depicted by the dotted fill in FIG. 11A(vi). Thus, the first phase change material **825A** loosens its grip on the first region **805_1** of the stick **805**. The signal **1033B** remains at the OFF amplitude, which means that the second phase change material **825B** is maintained at the temperature TB that is below the first transition temperature T1, and the second phase change material **825B** of the second gripping apparatus **800B** is in the solid state, as depicted by the grid fill in FIG. 11A(vi). Thus, the second phase change material **825B** grips the second region **805_2** of the stick **805**. The signal **1032** remains at a HIGH amplitude or level, and the voltage applied to the actuator drive **842** is at the HIGH amplitude, which means that the actuator drive **842** remains in the expanded state. The stick **805** remains stationary at this time relative to the z axis even though the grip on the stick **805** is loosened at the first region **805_1** because the stick **805** is gripped at the second region **805_2** and the actuator drive **842** is stationary.

At time (vii), the signal **1033A** remains at the ON amplitude, which means that the first phase change material **825A** is at a temperature TA that is above the second transition temperature T2, and the first phase change material **825A** is in a liquid state, as depicted by a dotted fill in FIG. 11A(vii). Thus, the first phase change material **825A** remains in a state

in which its grip on the first region **805_1** of the stick **805** is loosened. The signal **1033B** remains at the OFF amplitude, which means that the second phase change material **825B** is maintained at the temperature **TB** that is below the first transition temperature **T1**, and the second phase change material **825B** is in the solid state, as depicted by a grid fill in FIG. 11A(vii). Thus, the second phase change material **825B** grips the second region **805_2** of the stick **805**. The signal **1032** changes from the HIGH amplitude to the LOW amplitude, and the voltage applied to the actuator drive **842** switches to the LOW amplitude, which means that the actuator drive **842** changes to the contracted state. The stick **805** moves or translates along the +z direction as the second end **842_2** of the actuator drive **842** is moved along the +z direction relative to the first end **842_1** of the actuator drive **842** because the second gripping apparatus **800B** is fixed to the second end **842_2** of the actuator drive **842**.

At time (viii), the signal **1033A** has been switched to the OFF amplitude, and enough time has passed so that the first phase change material **825A** has reached a temperature **TA** that is below the first transition temperature **T1**, and the first phase change material **825A** is now in the solid state, as depicted by the grid fill in FIG. 11A(viii). Thus, the first phase change material **825A** has switched to the state in which it grips the first region **805_1** of the stick **805**. The signal **1033B** remains at the OFF amplitude, which means that the second phase change material **825B** is at the temperature **TB** that is below the first transition temperature **T1**, and the second phase change material **825B** is in the solid state. Thus, the second phase change material **825B** grips the second region **805_2** of the stick **805**. The signal **1032** remains at the LOW amplitude, which means that the actuator drive **842** is maintained in the contracted state. The stick **805** remains stationary at this time because the stick **805** is gripped at the first region **805_1** and at the second region **805_2**.

With reference to FIG. 12A, a side cross-sectional view of the positioning apparatus **840** is shown at eight distinct times [(i), (ii), (iii), (iv), (v), (vi), (vii), (viii)] in a signal cycle in which the stick **805** remains stationary relative to the z axis even though the actuator drive **842** is operating to expand and contract. FIG. 12B is a timing diagram showing the corresponding three signal amplitudes (**1033A**, **1033B**, and **1032**) versus time (in arbitrary units).

In general, the stick **805** remains stationary at all times in this signal cycle because the signal **1033A** provided to the first temperature adjusting device **815A** remains at an OFF amplitude and thus the first phase change material **825A** remains in a solid phase state, which means that it is always gripping the first end **842_1** of the actuator drive **842**. This is depicted in FIG. 12A by the grid fill in the first phase change material **825A**. The first gripping apparatus **800A** is therefore fixed to the first end **842_1** of the actuator drive **842** at all times, and because the first end **842_1** remains stationary, the first region **805_1** of the stick **805** remains stationary.

Moreover, in order to prevent breakage because of the motion of the second end **842_2** of the actuator drive **842**, the signal **1033B** is adjusted in coordination with the signal **1032**, as follows. The signal **1033B** is switched an ON amplitude at time (i) and enough time is allowed to pass so that at time (ii), the second phase change material **825B** of the second gripping apparatus **800B** reaches a temperature **TB** that is above the second transition temperature **T2** and is in the liquid state. This is done in advance of the translation of the second end **842_2** along the -z direction of the actuator drive **842** at time (iii). In this way, the second end

842_2 of the actuator drive **842** can move at time (iii) without applying a force to the stick **805** in the -z direction. Then, the signal **1033B** is switched to an OFF amplitude, and after a period of time from this, at time (iv), the second phase change material **825B** has managed to cool down enough and drops below the first transition temperature **T1** so that the second phase change material **825B** is now in a solid state, as depicted by the grid fill in FIG. 12A(iv).

At time (v), the signal **1033B** is adjusted to an ON amplitude and after enough time has elapsed, at time (vi), the second phase change material **825B** of the second gripping apparatus **800B** reaches a temperature **TB** that is above the second transition temperature **T2** and is in the liquid state, as depicted by the dotted fill in FIG. 12A(vi). This is done in advance of switching the signal **1032** to a LOW amplitude or level at time (vii), which causes the translation of the second end **842_2** along the +z direction of the actuator drive **842** at time (vii) to enable the second end **842_2** of the actuator drive **842** to move at time (vii) without applying a force to the stick **805** in the +z direction. The signal **1033B** is again switched to an OFF amplitude, and after a period of time from this, at time (viii), the second phase change material **825B** has managed to cool down enough and drops below the first transition temperature **T1** so that the second phase change material **825B** is now in a solid state, as depicted by the grid fill in FIG. 12A(viii).

In general, if top (the first) temperature adjusting device **815A** remains at an OFF amplitude and the bottom (the second) temperature adjusting device **815B** is at an ON amplitude, then the stick **805** is fixed in the axial direction. In general, if top (the first) temperature adjusting device **815A** is at an ON amplitude and the bottom (the second) temperature adjusting device **815B** is at an OFF amplitude, then the stick **805** is movable in the axial direction. In these implementations, the first temperature adjusting device **815A** and the second temperature adjusting device **815B** are never at the ON amplitude or the OFF amplitude at the same time during motion of the stick **805**.

Referring also to FIG. 13, a positioning apparatus **1360** is designed to independently translate each stick of a plurality of sticks **1305i**, **1305ii**, **1305iii**, etc. along an axial direction of that stick using a single actuator drive **1342** movable along its own axial direction **1310**, which is parallel with the z axis. The sticks **1305i**, **1305ii**, **1305iii** are shown for reference in FIG. 13 but are not necessarily a part of the positioning apparatus **1360**. Moreover, while three sticks **1305i**, **1305ii**, **1305iii** are shown, fewer or greater than three sticks can be controlled by the positioning apparatus **1360**.

The positioning apparatus **1360** includes a plurality of axial holders **1365i**, **1365ii**, **1365iii**, etc. Each axial holder **1365i**, **1365ii**, **1365iii** is configured to receive a respective stick **1305i**, **1305ii**, **1305iii**. Additionally, each axial holder **1365i**, **1365ii**, **1365iii** is fixed to the actuator drive **1342** at respective fixing mechanisms **1366i**, **1366ii**, **1366iii**.

The positioning apparatus **1360** includes a controller **1345** in communication with the single actuator drive **1342** (for example, via the sub-controller **1331**), and with the plurality of axial holders **1365i**, **1365ii**, **1365iii** (for example, via a sub-controller **1330**). The controller **1345** is configured to provide an actuation signal to the single actuator drive **1342** (by way of the sub-controller **1331**). The controller **1345** is also configured to provide at least one independent signal to each of the axial holders **1365i**, **1365ii**, **1365iii** by way of the sub-controller **1330**. The position of each stick **1305i**, **1305ii**, **1305iii** can be independently adjustable along its respective axial direction (which is parallel with the z axis and the axial direction **1310**) by the adjustment of the

provided at least one independent signal to each of the axial holders **1365i**, **1365ii**, **1365iii** without adjusting the provided actuation signal to the single actuator drive **1342**, as long as each axial holder **1365i**, **1365ii**, **1365iii** is thermally independent of the other axial holders **1365i**, **1365ii**, **1365iii**.

In particular, the actuation signal to the actuator drive **1342** can be a temporally-varying signal that toggles between a low amplitude (in which the voltage applied to the actuator drive **1342** is relatively low) and a high amplitude (in which the voltage applied to the actuator drive **1342** is relatively high).

In some implementations, the positioning apparatus **1360** is designed like the positioning apparatus **1460** of FIGS. **14** and **15**. Each axial holder **1465i**, **1465ii**, **1465iii** is configured to receive a respective stick **1405i**, **1405ii**, **1405iii**. Moreover, each axial holder **1465i**, **1465ii**, **1465iii** is defined by a pair of respective first and second gripping apparatuses (**1400iA**, **1400iB**), (**1400iiA**, **1400iiB**), and (**1400iiiA**, **1400iiiB**). For example, the axial holder **1465i** is defined by a portion of the first gripping apparatus **1400iA** and the second gripping apparatus **1400iB**; the axial holder **1465ii** is defined by a portion of the first gripping apparatus **1400iiA** and the second gripping apparatus **1400iiB**; and the axial holder **1465iii** is defined by a portion of the first gripping apparatus **1400iiiA** and the second gripping apparatus **1400iiiB**. While three axial holders **1465i**, **1465ii**, **1465iii** are shown in this implementation, it is possible for the positioning apparatus **1460** to have more than or fewer than three axial holders.

The distance *d* between the sticks **1305i**, **1305ii**, **1305iii** is determined depending on the application or the use of the sticks **1305i**, **1305ii**, **1305iii** and also is configured to provide for independent thermal control of the sticks **1305i**, **1305ii**, **1305iii**. This means that the distance *d* (relative to the extent or diameter of each stick) is great enough to enable independent thermal control of each stick. When one stick is being controlled, the axial holder **1365** associated with that stick includes a phase change material that is heated or cooled. The distance *d* is great enough so that the heating or cooling of the phase change material of one axial holder (associated with a particular stick) is thermally insulated or independent from the phase change material(s) of another axial holder associated with another stick. Indeed, the distance *d* is large enough to ensure thermal insulation between the sticks to enable heating of the phase change material(s) associated with a plurality of sticks that are adjacent to a particular stick in which the phase change material(s) of that particular stick is kept at a relatively cooler temperature. The distance *d* can depend on other factors such as a size or volume of the phase change material or an application of use for the positioning apparatus **1360**. To the extent that heat flows between the phase change materials of each axial holder or if each axial holder begins at a different temperature at a beginning of a cycle, the heating amplitudes and durations of heating can be adjusted such that all of the phase change material that is intended to melt does so at the same time and any excess heat reaching those not intended to melt is reduced or minimized.

For example, *d* can be on the order of a few times the size or extent (for example, a diameter) of the sticks. The distance *d* can be 3-6 times the value of the diameter of the sticks. Thus, if the diameter of each of the sticks is about 100 μm , then the distanced between the sticks can be about 250-1000 μm .

The first gripping apparatus **1400iA** is configured to interact with (grip and release) a first region of the stick **1405i** and the second gripping apparatus **1400iB** is config-

ured to interact with (grip and release) a second region of the stick **1405i**. The first gripping apparatus **1400iiA** is configured to interact with (grip and release) a first region of the stick **1405ii** and the second gripping apparatus **1400iiB** is configured to interact with (grip and release) a second region of the stick **1405ii**. Lastly, the first gripping apparatus **1400iiiA** is configured to interact with (grip and release) a first region of the stick **1405iii** and the second gripping apparatus **1400iiiB** is configured to interact with (grip and release) a second region of the stick **1405iii**.

Additionally, each axial holder **1465i**, **1465ii**, **1465iii** is fixed to the actuator drive **1442** by fixing each of the respective first gripping apparatuses **1400iA**, **1400iiA**, **1400iiiA** and each of the second gripping apparatuses **1400iB**, **1400iiB**, **1400iiiB** to the actuator drive **1442**. One way to accomplish this is to arrange the first gripping apparatuses **1400iA**, **1400iiA**, **1400iiiA** on a shared first substrate **1420A** and to arrange the second gripping apparatuses **1400iB**, **1400iiB**, **1400iiiB** on a shared second substrate **1420B**. In this way, the axial holders **1465i**, **1465ii**, **1465iii** are fixed to the actuator drive **1442** by way of a shared fixing mechanism **1466** that includes both the first substrate **1420A** and the second substrate **1420B**. The first substrate **1420A** is fixed to the first end **1442_1** of the actuator drive **1442** and the second substrate **1420B** is fixed to the second end **1442_2** of the actuator drive **1442**.

The gripping apparatuses (**1400iA**, **1400iB**) associated with the axial holder **1465i** are aligned with each other along the axial direction which is parallel with the *z* axis. In this way, the stick **1405i** that is received in the axial holder **1465i** is free to translate along the *z* axis with minimal forces applied in the directions perpendicular to the *z* axis. Similarly, the gripping apparatuses (**1400iiA**, **1400iiB**) associated with the axial holder **1465ii** are aligned with each other along the axial direction which is parallel with the *z* axis. In this way, the stick **1405ii** that is received in the axial holder **1465ii** is free to translate along the *z* axis with minimal forces applied in the directions perpendicular to the *z* axis. Lastly, the gripping apparatuses (**1400iiiA**, **1400iiiB**) associated with the axial holder **1465iii** are aligned with each other along the axial direction which is parallel with the *z* axis. In this way, the stick **1405iii** that is received in the axial holder **1465iii** is free to translate along the *z* axis with minimal forces applied in the directions perpendicular to the *z* axis.

Each of the first gripping apparatuses **1400iA**, **1400iiA**, **1400iiiA** is designed similarly to the first gripping apparatus **800A** in that it contains a first phase change material such as **825A** that is configured to receive a first region of the respective stick **1405i**, **1405ii**, **1405iii** and also a first temperature adjusting device such as **815A** that is received in the first substrate **1420A**. Each first temperature adjusting device in each first gripping apparatus **1400iA**, **1400iiA**, **1400iiiA** is in communication with a sub-controller **1430A**, which is in communication with the controller **1445**. The first phase change material is thermally coupled with the first temperature adjusting device such that a temperature change in the first temperature adjusting device causes a temperature change in the first phase change material.

Each of the second gripping apparatuses **1400iB**, **1400iiB**, **1400iiiB** is designed similarly to the second gripping apparatus **800B** in that it contains a second phase change material such as **825B** that is configured to receive a second region of the respective stick **1405i**, **1405ii**, **1405iii** and also a second temperature adjusting device such as **815B** that is received in the second substrate **1420B**. Each second temperature adjusting device in each second gripping apparatus

1400iB, 1400iiB, 1400iiiB is in communication with a sub-controller 1430B, which is in communication with the controller 1445. The second phase change material is thermally coupled with the second temperature adjusting device such that a temperature change in the second temperature adjusting device causes a temperature change in the second phase change material.

The controller 1445 (by way of the sub-controller 1431) provides the actuation signal to the single actuator drive 1442. For example, the actuation signal can be temporally-varying like the signal 1032 (with reference to FIG. 10B). This temporally-varying signal 1032 controls an axial position associated with the single actuator drive 1442.

Additionally, the controller 1445 can provide an independent signal (or signals) to each of the axial holders 1465i, 1465ii, 1465iii. This can be accomplished by sending a first signal to the first gripping apparatus 1400iA, 1400iiA, or 1400iiiA via the sub-controller 1430A and sending a second signal to the second gripping apparatus 1400iB, 1400iiB, or 1400iiiB via the sub-controller 1430B. In particular, the independent signal that is provided to a gripping apparatus is actually provided to the temperature adjusting device associated with that gripping apparatus, and the state of a particular phase change material is selected by adjustment of the provided independent signal to the temperature adjusting device thermally coupled with the phase change material.

In operation, the positioning apparatus 1360 (and 1460) is used to independently control the position of each stick 1305i, 1305ii, 1305iii along its respective axial direction and using only a single actuator drive 1342. FIGS. 16A-16E show examples of various configurations of the sticks 1305i, 1305ii, 1305iii. The sticks 1305i, 1305ii, 1305iii are positioned relative to an element 1670. As discussed above, the sticks 1305i, 1305ii, 1305iii can be used as actuators to effect or modify one or more characteristics of the element 1670. For example, each stick 1305i, 1305ii, 1305iii can include an electrical conductor (such as a cable or wire); a measurement probe; a capillary tube; an optical waveguide; an optical fiber; a carbon fiber or filament; or a sonic waveguide. If the stick 1305i, 1305ii, 1305iii is a measurement probe, then it could include an electrical testing probe, a silicon probe, an electrical recording probe, or an ultrasonic probe. In some implementations, one or more of the sticks 1305i, 1305ii, 1305iii can be of a first type (such as an electrical conductor (such as a cable or wire)) while one of the sticks can be of a second type (such as a measurement probe; a capillary tube; an optical waveguide; an optical fiber; a carbon fiber or filament; or a sonic waveguide). Thus, it is possible for a particular positioning apparatus 1360, 1460 to include sticks of different types.

For example, in FIG. 16A, each of the sticks 1305i, 1305ii, 1305iii is at the same axial position (along the z direction) relative to the element 1670 and in this case the sticks 1305i, 1305ii, 1305iii are all separated from the element 1670. In FIG. 16B, each of the sticks 1305i, 1305ii, 1305iii is at the same axial position relative to the element 1670 and in this case, the sticks 1305i, 1305ii, 1305iii are interacting with the element 1670 at a first interacting axial position. In FIG. 16C, sticks 1305i, 1305ii are interacting with the element 1670 at the first interacting axial position and the stick 1305iii is interacting with the element 1670 at a second interacting axial position. In FIG. 16D, the stick 1305i is interacting with the element 1670 at the first interacting axial position and the sticks 1305ii, 1305iii are interacting with the element 1670 at the second interacting axial position. In FIG. 16E, the sticks 1305i, 1305iii are separated from the element 1670 at the same axial position

and the stick 1305ii is interacting with the element 1670 at the first interacting axial position.

FIGS. 17A-17D show implementations of the placement and geometry of axial holders (such as 1400iA, 1400iiA, 1400iiiA) on a first substrate (such as the first substrate 1420A) to be used in a positioning apparatus (such as the positioning apparatus 1460). In FIG. 17A, a substrate 1720 such as a printed circuit board or PCB includes a blank region BR (such as the substrate 120 shown in FIG. 7A). Also shown in FIG. 17A is a controller 1730.

In FIG. 17B, sixteen open regions 1722 are formed, each open region 1722 having a circular cross section and being placed within the previously blank region BR of the substrate 1720. This is similar to the formation of the open region 122 in the substrate 120 of FIG. 7B. For example, the open regions 1722 can be holes drilled into the blank region BR. The PCB can include thermally-conductive and sinking metal planes slightly separated from the open regions 1722 to facilitate heat transfer away from the open regions 1722 in use.

In FIG. 17C, sixteen temperature adjusting devices 1715 are formed to be held within the substrate 1720 (for example, in each of the open regions 1722). For example, the temperature adjusting devices 1715 can be a resistive material epoxied into each open region 1722, which can be soldered at FIG. 17D. This is similar to the step shown in FIG. 7C. A close-up of one of the temperature adjusting devices 1715 and open regions 1722 is shown in FIG. 17D.

FIGS. 18A, 18B, and 18D show perspective views of a positioning apparatus 1860 designed like the positioning apparatus 1360 of FIG. 13 and the positioning apparatus 1460 of FIG. 14. The positioning apparatus 1860 includes a set of axial holders configured to receive a respective stick 1805 (collectively designated as 1805 in FIG. 18A, 18B, 18D). Each axial holder is defined by a pair of respective first and second gripping apparatuses (collectively designated as 1800A, 1800B. For example, each axial holder is defined by a portion of the first gripping apparatus 1800A and the second gripping apparatus 1800B. Each of the first gripping apparatuses 1800A is formed on a shared substrate 1820A and each of the second gripping apparatuses 1800B is formed on a shared substrate 1820B.

The positioning apparatus 1860 is designed to independently translate each stick of the plurality of sticks 1805 along an axial direction of that stick using a single actuator drive 1842 movable along its own axial direction, which is parallel with the z axis, and under control of a controller 1845, as discussed above. The controller 1845 is in communication with the single actuator drive 1842, and with the plurality of axial holders via a sub-controller that includes components 1830.

FIGS. 18C and 18E show the sticks 1805 that are positionable with the positioning apparatus 1860.

FIG. 19A shows a schematic of the placement and geometry of axial holders (such as 1400iA, 1400iiA, 1400iiiA) on a first substrate (such as the first substrate 1420A) to be used in a positioning apparatus (such as the positioning apparatus 1460). In FIG. 19A, eight axial holders are shaped with a circular cross section and are within an area 1990A of substrate 1920A and details of the area 1900A are shown in FIG. 19B. The design of the axial holders in area 1990A uses a chip resistor 1915 embedded within an open region 1922 that receives a phase change material. This is similar to the design shown in FIGS. 5A and 5B. The chip resistor 1915 is controlled by a controller (such as controller 130), which

includes the power source that supplies the current to the chip resistor **1915** by way of electrically conductive elements **1916, 1917**.

In some implementations the gripping apparatus **100** is a stick gripper including a stick such as a probe. The stick gripper includes an electrically-connected resistive via (as a temperature adjusting device) in a board (such as a printed circuit board) filled with a phase change material **125** (for example, a wax or paraffin). When no current from a power supply flows through the resistive via, the phase change material **125** in the via is in a solid state and the probe in the via is gripped. When the current flows through the resistive via, the phase change material **125** in the via changes to the liquid state (melts) and the probe in the via is released. The phase change material **125** in the liquid state remains in the via due at least in part to the capillary action. The grip and release action of the gripper is controlled electronically. The resistive via can be made of a plated or deposited resistive material in the board via, chip resistor adjacent to the board via, wire-wound resistor in the board via, or carbon paste coated in the board via.

In other implementations, a positioning apparatus (such as the apparatus **840** or the apparatus **1360**) is based on the gripping apparatus **100** that is capable of independently moving multiple probes along one axis using a single mechanical (for example, screw based drive), electrical (for example, piezoelectric actuator or stepper motor), or thermal (for example, shape memory alloy) positioner. The positioning apparatus includes two parallel substrates (or boards such as printed circuit boards) with a single (such as the apparatus **840**) or an array of resistive vias aligned along one axis (such as the apparatus **1360**). One board is fixed/immobile while another board is movable/mobile by a positioner/actuator (the actuator drive **842** or **1342**). By electronically controlling the current through the aligned vias (and therefore the grip or release of the probes in the vias) in the respective top and bottom boards, each probe held in the device can be independently translated in either direction (up or down or fixed in position) with a single mechanical or electronic actuator. The probes in the board vias moved by the device can be of any shape, as the liquid phase change material in the board via that grips the probe conforms to the probe shape.

Examples of the stick **105, 805, 1305i, ii, iii** include electrical testing probes, optical fibers, silicon probes, glass pipette/capillary, carbon fibers, electrical recording probes, and ultrasonic probes. The positioning apparatus and gripping apparatus can be constructed from non-ferrous parts and therefore can be made MRI compatible. The wire electrodes and glass capillary pipette electrodes for neural cell electrical spike detection, and applications in which one or multiple closely spaced probes need to be translated, positioned, or targeted with high precision are envisioned with this probe gripper principle and positioner device.

The choice of the phase change material in the board vias can be made so that the device is operational at different operating temperatures (low temperature operation, room temperature operation, physiological temperature operation, high temperature operation).

The gripping apparatus **100**, the positioning apparatus **840**, and the positioning apparatus **1360** have the following benefits. For example, a plurality of probes can be independently positioned with single positioner/actuator, such as, for example, shown in FIG. **13**, and because of this size, cost, and complexity can be reduced while density can be increased relative to prior designs.

Each gripping apparatus **100** (which includes the phase change material **125**, the temperature adjusting device **115**, and the substrate **120** can be made small and has a simple design, and many of these gripping apparatuses can be packed next to each other to form a positioning apparatus such as the positioning apparatus **860**. For example, micron-scale independent positioning of each stick **1305i, 1305ii, 1305iii** in the positioning apparatus **1360** can be obtained with an electric/motorized actuator drive **1342** (which can be a positioner such as, for example, a piezoelectric actuator). Accordingly, there is potential for significant miniaturization and weight reduction.

The phase change material **125** remains in the open region **122** of the substrate **120** at least in part due to capillary action.

Any of the apparatuses (gripping apparatus **100**, positioning apparatus **840**, and positioning apparatus **1360**) can be made to be fully electronically operational which allows remote control and automation of the apparatuses.

Technology that is implemented on a substrate **120** that is a printed circuit board is well-developed and inexpensive.

The gripping apparatus **100** can be designed to interact with a stick **105** of different shapes or application. For example, the stick **105** or one or more of the sticks used in the positioning apparatus **1360** can be an electrical probe, a silicon probe, a glass pipette, a carbon or optical fiber, an ultrasonic probe. In general, any stick **105** that is stiff enough to be grabbed by the phase change material **125** can be used.

The gripping apparatus **100**, positioning apparatus **840**, and positioning apparatus **1360** can be made of non-ferrous components, which potentially make these apparatuses compatible with magnetic resonance imaging machines. Additionally, the choice of phase change material **125** in the apparatuses allows for operation at different temperatures chosen based on the application.

The gripping apparatus **100**, and the positioning apparatuses **840, 1360** find applications in neuroscience where independent positioning of many probes in the brain is desired. Multiple probes can be independently positioned with single translator (actuator drive) as opposed to plural translators. Simplicity, miniature gripper size, low cost, low weight, high positioning precision, variety of probes that can be gripped and translated, and fully electronic operation add to the valuable features of the gripping apparatus **100** and the positioning apparatuses **840, 1360**.

What is claimed is:

1. A gripping apparatus comprising:

- a temperature adjusting device held in a substrate wherein the substrate defines an open region;
- a phase change material held within the open region and thermally coupled with the temperature adjusting device such that a temperature change in the temperature adjusting device causes a temperature change in the phase change material; and
- a controller connected to the temperature adjusting device and configured to send a signal to the temperature adjusting device to change its temperature and thereby change the temperature of the phase change material that is thermally coupled with the temperature adjusting device;

wherein:

- when the phase change material is at a temperature below a first transition temperature, the phase change material is in a solid state and the phase change material is configured to grip a stick within the phase change material; and

29

when the phase change material is at a temperature above a second transition temperature, the phase change material is in a liquid state and the phase change material is configured to loosen its grip on the stick such that the stick is capable of moving through the phase change material.

2. The gripping apparatus of claim 1, wherein the stick extends through the phase change material.

3. The gripping apparatus of claim 1, wherein the phase change material includes one or more of: wax; paraffin wax; and alkane hydrocarbon.

4. The gripping apparatus of claim 3, wherein the alkane hydrocarbon includes one or more of: n-octacosane, n-heptacosane, n-hexacosane, n-pentacosane, n-tetracosane, n-docosane, n-tricosane, n-heneicosane, n-eicosane, n-nonadecane, n-octadecane, n-heptadecane, n-hexadecane, n-pentadecane, n-tetradecane, and n-tridecane.

5. The gripping apparatus of claim 1, wherein the phase change material is selected so that the transition between the solid state and the liquid state at the first or second transition temperature occurs at an operating temperature for the gripping apparatus.

6. The gripping apparatus of claim 1, wherein the stick is rigid enough to withstand motion through the phase change material without fracturing or bending or kinking.

7. The gripping apparatus of claim 1, wherein the first transition temperature and the second transition temperature are at room temperature, at a temperature of a living organism, at a temperature below room temperature, or at a temperature above room temperature.

8. The gripping apparatus of claim 1, wherein the stick includes one or more of: at least one conductor; at least one measurement probe; at least one capillary tube; at least one optical waveguide; and at least one carbon fiber; and at least one sonic waveguide.

9. The gripping apparatus of claim 8, wherein the at least one measurement probe includes an electrical testing probe, a silicon probe, an electrical recording probe, or an ultrasonic probe.

10. The gripping apparatus of claim 1, wherein the substrate is generally defined in an x-y plane, and when the phase change material is at a temperature above the second transition temperature, the stick is capable of moving through the phase change material along a z axis that is perpendicular to the x-y plane.

11. The gripping apparatus of claim 1, wherein a cross section of the stick taken along a plane is a circular shape, a polygonal shape, or an irregular asymmetric shape.

12. The gripping apparatus of claim 1, wherein the temperature adjusting device comprises a resistive conductive wire and the controller includes a power source that supplies a current to the resistive conductive wire, wherein the resistive conductive wire changes its temperature as the current is changed.

13. The gripping apparatus of claim 1, wherein the temperature adjusting device comprises one or more of: a resistive material deposited in the open region of the substrate; a chip resistor adjacent to the open region of the substrate; a wire-wound resistor in the open region of the substrate; and a carbon paste coated in the open region of the substrate.

14. The gripping apparatus of claim 1, wherein the substrate includes a printed circuit board.

15. The gripping apparatus of claim 1, wherein the phase change material is held within the open region by way of capillary forces.

30

16. The gripping apparatus of claim 1, wherein the phase change material remains within the open region even if it is in the liquid state.

17. The gripping apparatus of claim 1, wherein the first transition temperature is equal to the second transition temperature.

18. A positioning apparatus comprising:

a single actuator drive movable along an axial direction; a plurality of axial holders, each axial holder configured to receive a stick and each axial holder being fixed to the single actuator drive; and

a controller in communication with the single actuator drive and with the plurality of axial holders, and configured to:

provide an actuation signal to the single actuator drive; and

provide at least one independent signal to each of the axial holders;

whereby the position of each stick is independently adjustable along the axial direction by the adjustment of the provided at least one independent signal to each of the axial holders without adjusting the provided actuation signal to the single actuator drive.

19. The positioning apparatus of claim 18, wherein: the single actuator drive includes a first end and a second end; and

the first and second ends are movable relative to each other along the axial direction.

20. The positioning apparatus of claim 19, wherein: each axial holder includes a first gripping apparatus fixed to the first end of the single actuator drive and a second gripping apparatus fixed to the second end of the single actuator drive;

the second gripping apparatus is aligned along an axial direction with the first gripping apparatus; and for each axial holder:

the first gripping apparatus is configured to receive a first region of the stick that is received in that axial holder and the second gripping apparatus is configured to receive a second region of the stick that is received in that axial holder.

21. The positioning apparatus of claim 20, wherein, for each axial holder:

the first gripping apparatus includes a phase change material that is configured to receive the first region of the stick that is received in that axial holder; and the second gripping apparatus includes a phase change material that is configured to receive the second region of the stick that is received in that axial holder.

22. The positioning apparatus of claim 18, wherein: providing the actuation signal to the single actuator drive comprises providing a temporally-varying signal to the single actuator drive, the temporally-varying signal controlling an axial position associated with the single actuator drive.

23. The positioning apparatus of claim 18, wherein: each axial holder is configured to interact with at least two interaction regions of its associated stick;

at each interaction region, the stick is received in a gripping apparatus; and

providing at least one independent signal to each of the axial holders comprises providing an independent signal to each gripping apparatus in each axial holder.

24. The positioning apparatus of claim 23, wherein each gripping apparatus comprises: a temperature adjusting device; and

31

a phase change material thermally coupled with the temperature adjusting device such that a temperature change in the temperature adjusting device causes a temperature change in the phase change material;
 wherein providing the independent signal to a gripping apparatus comprises providing an independent signal to the temperature adjusting device, and the state of the phase change material is selected by adjustment of the provided independent signal to the temperature adjusting device thermally coupled with the phase change material.
 25. A method comprising:
 providing a single actuation signal to a single actuator drive, wherein the single actuation signal controls a movement of the single actuator drive along an axial direction;
 providing an independent signal to each axial holder of a plurality of axial holders, wherein each axial holder receives a stick and each axial holder is fixed to the single actuator drive; and
 independently adjusting a position of a stick along the axial direction by adjusting the provided independent signal to the axial holder that receives that stick and without adjusting the provided actuation signal to the single actuator drive.

32

26. The method of claim 25, wherein providing the single actuation signal to the single actuator drive comprises controlling a relative movement between a first end of the single actuator drive and a second end of the single actuator drive along the axial direction.
 27. The method of claim 25, wherein providing the single actuation signal to the single actuator drive comprises providing a temporally-varying signal to the single actuator drive, the temporally-varying signal controlling an axial position associated with the single actuator drive.
 28. The method of claim 25, wherein providing an independent signal to an axial holder comprises providing an independent signal to a gripping apparatus in that axial holder.
 29. The method of claim 28, wherein providing the independent signal to a gripping apparatus comprises providing an independent signal to a temperature adjusting device of the gripping apparatus; further comprising selecting a state of a phase change material thermally coupled to the temperature adjusting device by adjusting the provided independent signal to the temperature adjusting device thermally coupled with that phase change material.
