(57) **ABSTRACT**

According to an embodiment, an image elimination apparatus eliminates an image formed on a sheet. A sheet supply unit supplies the sheet on which the image is formed. A first reader reads the sheet supplied by the sheet supply unit. An image eliminator eliminates the image formed on the supplied sheet. A second reader reads the sheet passing through the image eliminator. A discharge unit stacks the sheet to be discharged. A controller causes the first reader to read the sheet at a first speed in order to judge whether the sheet is reusable or not based on the reading result of the first reader. The controller also causes the second reader to read the sheet at a second speed faster than the first speed in order to judge whether the image formed on the sheet has been eliminated or not based on the reading result of the second reader.

No. 8,538,317 on Sep. 17, 2013, which is based upon and claims the benefit of priority from U.S. Provisional Patent Application No. 61/112,649, filed on Nov. 7, 2008 and Japanese Patent Application No. 2009-176054, filed on Jul. 29, 2009; the entire contents of each of the applications are incorporated herein by reference.

FIELD OF THE INVENTION

The present invention relates to an image elimination apparatus for eliminating an image from a sheet with the image formed and enabling reuse of the sheet, an image eliminating method, and an image forming apparatus.

BACKGROUND OF THE INVENTION

In recent years, from the standpoint of resource usage by recycle, there is an increasing demand for an image forming and eliminating apparatus for enabling elimination of an image from a sheet with the image formed and reuse of the sheet. An apparatus for eliminating an image from a sheet with the image formed is disclosed in, for example, Japanese Patent Application Publication No. 8-6446.

However, even if the image is eliminated, whether the sheet itself with the image formed can be reused or not is not clear. Furthermore, after elimination, whether the image on the sheet is eliminated or not is unknown.

SUMMARY OF THE INVENTION

The present invention is intended to provide an image elimination apparatus having a function for judging whether a sheet intended to be reused is reusable or not, an image eliminating method, and an image forming apparatus.

To achieve the above advantage, the aspect of the present invention is to proved an image elimination apparatus comprising a first reader configured to read the status of a sheet, a first judgment portion configured to judge whether the read sheet is reusable or not, an image eliminator configured to eliminate the image formed on the sheet, a second reader configured to read the sheet passing through the image eliminator, a second judgment portion configured to judge whether the image formed on the sheet is eliminated or not, and a controller configured to controlling the first reader and the second reader so as to read with different reading precision.

To achieve the above advantage, the aspect of the present invention is to proved an image eliminating method comprising reading a status of a sheet and first judging whether the sheet is reusable or not, eliminating the image formed on the sheet, and second judging whether the image is elimi-

nated at the eliminating or not, wherein reading precision at the first judging and reading precision at the second judging are different from each other.

To achieve the above advantage, the aspect of the present invention is to proved an image forming apparatus comprising an image forming portion configured to form an image on a sheet and an image elimination apparatus configured to eliminate the image on the sheet formed by the image forming portion, wherein the image elimination apparatus includes a first reader configured to read the status of a sheet, a first judgment portion configured to judge whether the read sheet is reusable or not, an image eliminator configured to eliminate the image formed on the sheet, a second reader configured to read the sheet passing through the image eliminator, a second judgment portion configured to judge whether the image formed on the sheet is eliminated or not, and a controller configured to control the first reader and the second reader so as to read with different reading precision.

DETAILED DESCRIPTION OF THE INVENTION

Hereinafter, the first embodiment of the present invention will be explained with reference to FIGS. 1 to 5.

FIG. 1 is a schematic view of the image forming apparatus (hereinafter, abbreviated to MFP) 1 to which a post-processing device 3 having a built-in image elimination apparatus 2 of the present invention and FIG. 2 is an enlarged schematic view of the image elimination apparatus 2.

The MFP 1 forms an image on sheets supplied from a sheet cassette 4 and feeds the image-formed sheets to the post-processing device 3. The MFP 1, according to the user

input to a control panel **5**, on the sheets which are supplied one by one from the sheet cassette **4**, forms the image by an image forming portion **6**, for example, by an electrostatic photographic recording system. Further, the MFP **1**, using ink or toner using a coloring material which is achromatized by applying heat higher than a certain temperature for a predetermined period of time, forms the image on the sheets. The post-processing device **3**, for example, sorts or stables the sheets with the image formed by the MFP **1**.

The image elimination apparatus **2** includes a sheet supply tray **7**, a reader **9** and an image eliminator **10** which are installed along a first sheet conveying path **8**, a stack box **11** installed to abolish sheets judged as nonreusable, and a discharge port **12** for feeding sheets to the MFP **1**.

On the sheet supply tray **7**, the sheets with the image formed are stacked. The reader **9** has a CCD sensor **13**. The CCD sensor **13**, as described later, to judge whether the sheets are usable or not and the print of the sheets is eliminated or not, reads the surface of each of the sheets. The image eliminator **10** has internally a heater **14** and eliminates the image printed on the sheets by heat. On the first sheet conveying path **8**, a plurality of rollers **15** are installed and the sheets are conveyed by the plurality of rollers **15**. Further, on the first sheet conveying path **8**, a first flapper **16** and a second flapper **17** are installed. The first flapper **16** separates the sheets judged as nonreusable from the first sheet conveying path **8**. The sheets separated by the first flapper **16** are guided to the stack box **11**. Between the first flapper **16** and the stack box **11**, a first sensor **26** is installed. The second flapper **17** is installed immediately before the discharge port **12** to the MFP **1** and guides the sheets to a second sheet conveying path **18** for conveying again the sheets with the image eliminated by the image eliminator **10** to the reader **9**. Also on the second sheet conveying path **18**, the plurality of rollers **15** for conveying sheets are installed. On the image elimination apparatus **2**, a pick-up roller for taking out sheets one by one from the sheet supply tray **7** and feeding the sheets to the first sheet conveying path **8** is installed. Between the second flapper **17** and the discharge port **12**, a second sensor **27** is installed.

FIG. **3** is a block diagram showing the electrical connection of the image elimination apparatus **2**. To a CPU **19**, via a system bus **20**, a ROM **21**, a RAM **22**, the CCD sensor **13** of the reader **9**, the heater **14** of the image eliminator **10**, a flapper driver **23** for controlling the first flapper **16** and second flapper **17**, a sheet conveying motor **24**, a sheet supply motor **25**, and a sensor driver **28** for controlling the first sensor **26** and second sensor **27**. Further, the CPU **19** communicates with the MFP **1** by an interface **29** connected via the system bus **20**. In the ROM **21**, a program for operating the CPU **19**, a density threshold value used to decide the fold depth of sheets, a density threshold value for checking whether the image is eliminated from the sheets or not, and data of the print rate of the sheets which is an index of usable or unusable are stored. In the RAM **22**, the highest density of the image obtained when reading the status of a sheet and the position information indicating the highest density are stored. The CCD sensor **13** is arranged as a row of line sensors and detects the color shade of sheet. The heater **14** uses an IH heater and while the sheet passes through the image eliminator **10**, applies heat to the sheet and achromatizes the coloring material. The CPU **19** drives respectively the first flapper **16** and second flapper **17** via the flapper driver **23** and separates the sheet from the first sheet conveying path **8**.

FIGS. **4** and **5** are a flow chart showing the flow of the program stored in the ROM **21**. Firstly, a user instructs

image elimination of the sheet put on the sheet supply tray **7** from the control panel **5** (**30**). Then, the CPU **19** receives an elimination command from the MFP **1** via the interface **29** (**31**), in order to read the status of the sheet and eliminate surely the image from the sheet, sets the sheet conveying speed to a first speed (**32**), drives the heater **14** of the image elimination apparatus **2** (**33**), and drives the sheet conveying motor **24** (**34**). Next, the CPU **19** drives the sheet supply motor **25** (**35**), picks up one sheet from the sheets stacked on the sheet supply tray **7**, and feeds the sheet to the first sheet conveying path **8**.

The sheet fed to the first sheet conveying path **8** is guided to the reader **9** by the rollers **15**. At the point of time when the leading edge of the sheet reaches the reader **9**, the CCD sensor **13** of the reader **9** starts reading (**36**), during passing of the sheet through the CCD sensor **13**, reads the image on the sheet surface, and judges whether the sheet is usable or not (**37**). Hereinafter, an operation of reading the status of a sheet to judge the possibility of reuse such as existence of creases and corner folds of the sheet or a high print rate is referred to as first reading. If the first reading finds creases of the sheet or corner folds thereof or that the print rate is high, thus elimination is difficult, the sheet is judged as unusable. And, the CPU **19** drives the first flapper **16** (**38**), guides the sheet to the stack box **11**, and when judging that the sheet passes through the first sensor **26** installed at the entrance of the stack box **11** (**39**), finishes the elimination process (**40**). Further, in the case of the first reading, to store the highest density data and the position data indicating the density in the RAM **22** and in the case of reading to be executed after elimination of the image which will be described later, use the stored data is possible. The highest density is referred to as integration of either or both of the highest value of the print rate in divided several regions of the sheet and the highest value of the output of the CCD sensor **13**. The highest density is used in comparison of the density read by the reader **9** with the threshold value stored beforehand in the ROM **21**.

A sheet having corner folds may cause sheet jamming to the apparatus. The sheet having creases, due to the roughness of the sheet surface owing to creases, may cause variations in adhesion of toner and ink. A deeply folded sheet may also cause variations in toner adhesion. Therefore, the CPU **19**, to avoid a mechanical failure and a defective image quality, judges the sheet having creases or corner folds as nonreusable.

To a sheet judged as reusable by the first reading, that is, a crease-free sheet or a low-print-rate sheet, the image eliminator **10** applies heat by the heater **14** and eliminates the image. Hereafter, the CPU **19** drives the second flapper **17** (**41**) and guides the sheet passing through the image eliminator **10** to the first sheet conveying path **8** on the upstream side of the reader **9** via the second sheet conveying path **18**. Next, the CPU **19** sets the sheet conveying speed to a second speed higher than the first speed used when executing the first reading and image elimination (**42**), permits again the CCD sensor **13** of the reader **9** to read and pass the pixels, and checks whether the image is eliminated or not (**43**). Hereinafter, to read an image on a sheet by the CCD sensor **13** to check whether the image is eliminated or not is referred to as second reading. As the sheet conveying speed is increased, reading of the pixels becomes rough. Therefore, as the conveying speed when the sheet passes through the reader **9** is increased, the reading precision is lowered. Further, when executing the first reading, among the image formed on the sheet, the position data indicating the highest density is stored in the RAM **22** and when

executing the second reading, only the position indicating the highest density stored in RAM **22** and the periphery thereof are read and that the image is eliminated at the position can be judged, so that the entire image of the sheet is eliminated can be decided.

Here, the reason that the first reading precision is made higher than the second reading precision will be explained. As described before, at the time of the first reading, to read creases and corner folds of the sheet and the highest density and judge the possibility of reuse of the sheet is an object. The image elimination apparatus **2** itself cannot predict beforehand the location of creases or corner folds and the location indicating the highest density, and the density obtained from the part of creases or corner folds and the pattern shape thereof are usually irregular, and the contrast of the part of creases or corner folds is lower than that of the part with an image of characters formed. In order to judge existence of creases or corner folds, to read the entire sheet with such precision as to recognize the density, pattern shape, and contrast and reserve the processing time for judging the creases or corner folds is necessary. Therefore, to switch the sheet conveying speed to a considerably slow speed (for example, in consideration of perfect image elimination by the image eliminator **10** following the first reading, about 21 cm, which is the length of an A4-sized sheet in the lateral direction, per minute) is desired. As mentioned above, the first reading precision can be read at the conveying speed at the time of sheet elimination, so that as a result, the reading precision is improved extremely. On the other hand, in the second reading, that effective elimination of the image can be even recognized is desirable. For example, if the elimination object is a document image, the image is arranged almost regularly, so that there is no need to recognize as far as the density pattern shape and even if the image is read at such a speed as recognizing existence of the image, there are few problems imposed. Furthermore, the image elimination is executed for the entire sheet by taking time, so that if the elimination of the image at the location showing the highest density can be even recognized, that other images are also eliminated may be assumed.

In the second reading, when there exists a pixel indicating a predetermined density or higher on a sheet and that the image is not eliminated is judged, in order to drive the first flapper **16** and abolish the sheet, the CPU **19** guides the sheet to the stack box **11** and when judging that the sheet passes through the first sensor **26**, finishes the process (**40**). At **43**, there exists no pixel indicating the predetermined density or higher on the sheet and when judging that the image is eliminated, the CPU **19** returns the second flapper **17** (**44**) and guides the sheet from the discharge port **12** into the MFP **1**. When judging that the sheet passes through the second sensor **27** installed at the entrance of the MFP **1** (**45**), the CPU **19** finishes the elimination process (**46**).

Here, the sheet guided into the MFP **1** is stored in the sheet cassette **4** installed in the MFP **1**. The sheet stored in the sheet cassette **4**, by an instruction of selection of the sheet cassette from the control panel **5** of the MFP **1**, is used for image formation of the MFP **1**. Further, when not detecting that the sheet does not pass through the first sensor **16** or the second sensor **17** for a predetermined period of time after the sheet supply motor **25** for picking up the sheet from the sheet cassette **4** is driven, the CPU **19** displays an occurrence of sheet jamming in the image elimination apparatus **2** on the control panel **5** installed on the MFP **1** and notifies the sheet jamming to the user. Further, when the image elimination apparatus is not connected to the MFP **1** and has no display

unit, to notify no connection of the image elimination apparatus to the user by a warning sound or a voice is possible.

Further, when a plurality of sheets are set on the sheet supply tray **7**, if the heater **14** is repeatedly turned on or off each time, the life span of the heater is shortened. If the heater **14** is turned off once, there are possibilities of an occurrence of failure such that until the heater reaches an appropriate temperature after the heater is turned on thereafter, a long period of time is taken. Therefore, after the heater **14** is turned on, until the sheets on the sheet supply tray **7** are all used up, regardless of the possibility of reuse of the sheets, the heater **14** is kept on. And, the sensor installed on the sheet supply tray **7** detects that the sheets are all gone and then after confirming that the sheets pass through the heater **14**, the CPU **19** turns off the heater **14**.

By use of the aforementioned constitution, the reading for judging the possibility of reuse of the sheet on which the image is formed is executed with high precision, and the reading for checking image elimination is executed with lower precision, and the same reading portion is used for both readings, so that a small image elimination apparatus having a high processing speed can be provided.

Next, the second embodiment will be explained. In this embodiment, the explanation duplicated with the first embodiment will be omitted and the differences will be explained. In this embodiment, the image eliminator **10** has a number of elimination times recording portion **10a** for making a punch hole at a predetermined position of a sheet according to the number of elimination times after elimination of an image. The number of elimination times recording portion **10a** records the number of elimination times every image elimination. Hereafter, in the second reading, the reader **9** reads the density of the sheet image and the number of punch holes. FIGS. **6** and **7** show the flow charts of the operations of the image elimination apparatus in this embodiment, though they are the same operations as those at **30** to **37** shown in FIG. **4** of the first embodiment, so that the explanation thereof will be omitted. Hereinafter, the operations following the second reading will be explained. The second reading reads whether the image is eliminated or not and the number of punch holes. Here, when the sheet image is not eliminated and the CPU **19** judges from the status of the punch holes that as a result of comparison (**47**), the number of elimination times does not reach a predetermined number of times (N at **47**), the CPU **19** sets the sheet conveying speed to the first speed which is the same as that at the execution time of the first reading (**48**), then permits the sheet to pass again through the image eliminator **10**, eliminates the image, and records the number of elimination times. Hereafter, the CPU **19** drives the second flapper **17** (**41**), sets the second speed (**47**), permits the sheet to pass through the second sheet conveying path **18**, and executes again the second reading by the reader **9**. In the second reading, the reader **9** reads whether the image is eliminated or not and reads the number of punch holes. By reading the number of punch holes, the number of elimination times is judged (**47**). When judging that the number of elimination times reaches the predetermined number of times (Y at **47**), the CPU **19** drives the first flapper **16** (**38**), in order to abolish the sheet, guides the sheet to the stack box **11**, and finishes the elimination process (**40**). If the CPU **19**, from the number of punch holes read simultaneously in the second reading, judges that the number of elimination times does not reach the predetermined number of times, the CPU **19** guides the sheet to the MFP **1**.

By use of the aforementioned constitution, an image elimination apparatus for surely eliminating the image of a used sheet, when the number of elimination times reaches the predetermined number of times, abolishing the sheet, thereby removing a sheet of a large number of elimination times and of a deteriorated quality can be provided.

Next, the third embodiment equipped separately with the first reader and second reader will be explained.

FIG. **8** is a schematic view of the image elimination apparatus **2** relating to this embodiment. From the operation of reading the status that the sheet in this embodiment is a judgment material of possibility of use to the operation of image elimination and the operations after reading whether the image is eliminated from the sheet or not are almost the same as those of the first embodiment, so that the explanation will be omitted. The image elimination apparatus **2** of this embodiment is built in the post-processing device **3** similarly to the first embodiment, includes a sheet supply tray **60**, along a sheet conveying path **61**, a first reader **62** and an image eliminator **63**, and a second reader **64** on the downstream side of the image eliminator **63** on the sheet conveying path **61** and furthermore has a stack box **65** installed to abolish the sheet which comes off the sheet conveying path **61** and is judged as nonreusable.

Next, the operations will be explained. Firstly, if sheet elimination is instructed from the control panel of the MFP **1**, the CPU **19** turns on a heater **68** and rotates rollers **166**. Next, the CPU **19** picks up the sheets loaded on the sheet supply tray **60** one by one. And, the first reader **62** reads the image on the sheet surface and detects the status of creases of the sheet. Here, when the sheet is judged as nonreusable, the CPU **19** drives a flapper **66**, guides the sheet to the stack box **65**, confirms that the sheet passes through a sensor **67**, and then finishes the elimination process. On the other hand, while the sheet judged as reusable passes through the image eliminator **63**, the heater **68** applies heat to the sheet to eliminate the image. While the sheet passing through the image eliminator **63** passes furthermore through the second reader **64**, the CPU **19** checks whether the image on the sheet is eliminated or not. The second reading may be executed with lower precision than the first reading. Therefore, the density of the CCD used may be lowered than that of a CCD sensor installed in the first reader **62**. In the second reading, when that the image is not eliminated is judged, in order to abolish the sheet, the CPU **19** drives the flapper **66**, guides the sheet to the stack box **65**, confirms that the sheet passes through the sensor **67**, and then finishes the elimination process. On the other hand, the sheet judged that the image is eliminated is supplied to the MFP **1** and the elimination process is finished.

As mentioned above, the first reader **62** and second reader **64** are installed separately, thus there is no need to return the sheet again to the reader after image elimination. Therefore, the labor and time of returning the sheet to the reader are saved and there is no need to switch the sheet conveying speed, so that the image can be eliminated efficiently from the sheet and the sheet can be supplied quickly to the image forming apparatus.

In the present invention, furthermore, by use of the fourth embodiment indicated below, the processing efficiency can be improved. In this embodiment, the arrangement of the readers and image eliminators may be the same as that of either of the first embodiment and third embodiment, though the first embodiment will be explained as an example.

In this embodiment, when a predetermined number of sheets n to be processed first are all almost uniform and reusable, for the residual sheets, the first reading and elimi-

nation are executed by conveying at a slightly fast speed. FIGS. **9** and **10** show the flow charts of the operations of the image elimination apparatus **2** in this embodiment. Firstly, as an initial state, the speed for enabling highly precise reading and sure image elimination and the number of sheets to be processed 0 are set (**71**). Next, the status of the sheets is read by the first reader **62** (**72**) and the possibility of reuse is decided (**73**). Here, the sheets judged as unusable (N at **73**) are abolished (**74**). At the time of the first reading, for the first sheet, the first reader **62** reads the position indicating the highest density on the sheet and the information on the print condition of the sheet such as the density and stores the information in the RAM **22** installed in the apparatus (**75**, **76**). Next, according to the settings of the initial conditions stored beforehand in the ROM **21**, the first reader **62** executes the first reading and elimination of the image on the sheet. Here, if the read sheet is reusable and the print condition of the sheets such as the highest density of the first sheet stored in the RAM **22** is almost the same (**78**), the first reader **62** counts up the number of processed sheets (**79**). Until the counted-up number of processed sheets reaches the predetermined number of sheets n, the processing is continued in the state that the conditions such as the sheet conveying speed and the temperature of the heater **14** are kept straight as the initial conditions. When the counted-up number of processed sheets reaches the predetermined number of sheets n (**80**), that the residual sheets stacked on the paper supply tray **7** are all reusable, and the print condition is uniform, and the first reading precision for the residual sheets may be lowered smoothly, thus the sheet conveying speed relating to the first reading and elimination is set to a speed faster than the initial speed. Further, from the highest density of the image on the sheet stored in the RAM **22**, the CPU **19** obtains a necessary and sufficient temperature to eliminate the image indicating the highest density and sets the heater **14** to the temperature (**81**).

Hereafter, when the first reading (**72**), elimination (**82**), and second reading (**83**) are continued until the sheets on the paper supply tray **7** are all used up under the same conditions and that the sheets are all gone is detected (**87**), the CPU **19** finishes the process (**88**). On the other hand, when that between the first sheet and the "n"th sheet, there is at least one sheet which is not reusable or is different in the sheet status is judged, assuming the sheets stacked on the sheet supply tray **7** as non-uniform, the process is continued without changing the conditions such as the sheet conveying speed and the temperature of the heater **14** which are set first. Further, when that the sheet status is reusable and uniform is judged, the first reading may be omitted. Further, when the highest density of the sheet does not reach a preset value, assuming the image not to be printed, to turn off the heater **14** and not eliminate the image is possible. Furthermore, unless the image eliminator **10** changes the temperature of the heater **14**, from the read density of the image on the sheet, the passing speed of the sheet through the image eliminator **10** can be set. Further, when the first sheet to the "n"th sheet are judged to be almost uniform in the sheet status and the sheets after the "n"th sheet are read with the first reading precision lowered, if that the sheet status is different greatly is detected, to execute the first reading of the sheet under the initial conditions is possible.

In this embodiment, when the first sheet to the "n"th sheet are reusable and the sheet status is almost uniform, in the second reading, only the position indicating the highest density stored in the RAM **22** is decided as a reading object and the number of comparison times for checking whether the image is eliminated or not can be reduced. Furthermore,

to increase the sheet conveying speed before the sheet reaches the position indicating the highest density and after reading and improve the processing speed is possible.

According to the embodiment aforementioned, when eliminating sheets used in a conference in a batch, that is, when processing a large quantity of sheets in almost the same status at a time by the image elimination apparatus 2, there is no need to read the statuses one by one for all the sheets. Namely, only by checking only the preset status of the n sheets, the conditions such as the first reading speed and the set temperature of the heater 68 are set, so that the processing time can be reduced. Further, when eliminating the image, applying unnecessary heat to the sheet can be prevented. Therefore, the life span of the sheets can be lengthened and the power consumption can be reduced.

The present invention can realize furthermore high efficiency of the processing by the fifth embodiment indicated below. The fifth embodiment performs the processes from the first reading to image elimination for all the sheets stacked on a sheet supply tray 98. Thereafter, the second reading is performed for all the sheets with the image eliminated. FIG. 11 is a schematic view of the image elimination apparatus 2 relating to this embodiment. The constitution of the image elimination apparatus 2 does not include the second sheet conveying path as indicated in the first embodiment and instead, includes a second flapper 90 and a sheet tray 91. Hereinafter, the operation of the fifth embodiment will be explained. Firstly, the sheets are picked up one by one from the sheet supply tray 98 and a reader 97 reads whether the sheets are reusable or not. Next, the sheets are eliminated by a heater 93 of an image eliminator 92. In this embodiment, the sheets finishing the operations to image elimination are stacked on the sheet tray 91 by driving the second flapper 90. The operations from the first reading to stacking on the sheet tray 91 via elimination are performed until the sensor installed on the sheet supply tray 98 detects that the sheets stacked on the sheet supply tray 98 are all gone. Further, the sheets judged as nonreusable, similarly to the aforementioned embodiment, are guided to a stack box 95. After that the sheets on the sheet supply tray 98 are gone is detected and the first reading of the sheets and image elimination are finished, until the sheets are conveyed to the sheet tray 91, as soon as sufficient time elapses, the sheet tray 91 slides upward, and the heating of the heater 93 installed in the image eliminator 92 is finished. Next, the sheet tray 91 slides from the position where the sheet tray 91 is generally situated when the first reading and elimination are executed up to the position where the sheets can be supplied to a sheet conveying path 94. The sheet conveying speed is set to the second speed, and the sheets are picked up one by one from the slid sheet tray 91 onto the sheet conveying path 94, and the second reading is executed. Here, whether the image on each sheet is eliminated effectively or not is checked and the sheets that the image elimination cannot be confirmed are guided to the stack box 95.

Further, to install a pickup roller for picking up sheets from the sheet tray 91 with the sheet tray 91 fixed unless the sheet tray 91 slides, pickup the sheets stacked on the sheet tray 91 one by one, rotate a roller 96 in the opposite direction to the first reading, permit the roller 96 to pass through the reader 97, and check whether the sheet image is eliminated or not is possible. Further, in this case, the branch point to the entrance to the MFP 1 is installed on the upstream side (above the reader shown in FIG. 11) of the reader 97.

By use of this embodiment, in the case of a large number of processing sheets, only one switching of the first speed and second speed is sufficient, thus the processing time can be reduced. Further, at the time of the second reading, there is no need to turn on the heater 93, so that the power consumption can be reduced.

The present invention can be realized also by the sixth embodiment indicated next. FIGS. 12 to 14 are schematic views showing this embodiment. In the drawing, the arrows show the passing direction of sheets. Firstly, the sheet supplied from a sheet supply tray 104 is conveyed at the first speed, and as shown in FIG. 12, a reader 100 executes the first reading and detects the status of the sheet, and a heater 102 of an image eliminator 101 is heated, thus the image of the sheet is eliminated. The CPU 19, upon confirmation of passing of the sheet through the image eliminator 101, stops the sheet. And, the CPU 19 rotates a roller 103 in the opposite direction, conveys the sheet as shown in FIG. 13, and returns the leading edge of the sheet up to the start position of the reader 100. Next, the CPU 19 sets the conveying speed to the second speed, drives the roller 13 to permit the sheet to pass through the reader 100, and executes the second reading in order to check whether the image on the sheet is eliminated or not. Here, when at the time of the first reading, the sheet is reusable and at the time of the second reading, the image of the sheet is eliminated on a reusable level, the sheet is reusable by the MFP 1, thereby is conveyed to the sheet cassette 4 in the MFP 1. When judging at the time of the first reading that the sheet is not reusable or when judging at the time of the second reading that the image of the sheet is not eliminated on the reusable level, the CPU 19 conveys and abolishes the sheet at a stack box 111. Further, as shown in FIG. 14, when conveying the sheet in the opposite direction to the direction at the time of execution of the first reading and elimination, the elimination of the image may be checked. In this way, a conveying path is installed from above to the MFP 1 as shown in FIG. 14, thus the number of sheet conveying times can be reduced and the processing speed can be increased. In this embodiment, there is no need to install the second sheet conveying path as in the first embodiment, so that the possibility of reuse of used sheets can be executed at high precision, and the processing speed can be increased, and furthermore, the image elimination apparatus can be miniaturized.

As mentioned above, according to the present invention, an image elimination apparatus and an image eliminating method of judging the possibility of reuse of used sheets at high precision and at a fast processing speed can be provided.

What is claimed is:

1. An erasing apparatus comprising:
a sheet supply unit configured to supply a sheet on which an image is formed;
a sheet conveying unit configured to convey the sheet;
a reader arranged on the sheet conveying unit, and configured to read the sheet; and
an erasing unit arranged on the sheet conveying unit, and configured to perform an erasing process to erase the image formed on the sheet, wherein:
the sheet conveying unit includes a conveying roller controlled to:
before the erasing unit performs the erasing process on the sheet, convey the sheet through the reader at a first speed,
after the erasing unit performs the erasing process on the sheet, convey the sheet through the reader at a second speed faster than the first speed, and
after the reader reads the sheet at the second speed, convey the sheet to one of a first position and a

second position different from the first position, based on a condition of the sheet determined from an image of the sheet generated from the reader reading the sheet at the second speed.

2. The apparatus according to claim **1**, wherein the erasing unit performs the erasing processing to erase the image by using heat.

3. The apparatus according to claim **1**, wherein the sheet conveying unit includes a first sheet conveying path that extends from the sheet supply unit toward the first position and a second sheet conveying path that branches from the first sheet conveying path at a third position downstream side of the reader and that merges with the first conveying path at a fourth position between the sheet supply unit and the reader.

4. The apparatus according to claim **3**, further comprising a separating unit arranged at the third position on the first conveying path and configured to switch a conveying path of the sheet between the first sheet conveying path and the second sheet conveying path.

5. The apparatus according to claim **1**, wherein the condition of the sheet read by the reader is a defect of the sheet.

6. The apparatus according to claim **1**, wherein the condition of the sheet read by the reader is an unevenness or a printing rate.

7. The apparatus according to claim **1**, further comprising a recording unit for making a mark at a predetermined position of the sheet according to the number of erasing times after erasing the image.

8. The apparatus according to claim **7**, wherein the mark made by the recording unit is a punch hole.

9. An image forming apparatus comprising:

an image forming unit configured to form an image on a sheet;

a sheet supply unit configured to supply a sheet on which an image is formed;

a sheet conveying unit configured to convey the sheet;

a reader arranged on the sheet conveying unit, and configured to read the sheet;

an erasing unit arranged on the sheet conveying unit, and configured to perform an erasing process to erase the image formed on the sheet;

a first cassette; and

a second cassette, wherein:

the sheet conveying unit includes a conveying roller controlled to:

before the erasing unit performs the erasing process on the sheet, convey the sheet through the reader at a first speed,

after the erasing unit performs the erasing process on the sheet, convey the sheet through the reader at a second speed faster than the first speed, and

after the reader reads the sheet at the second speed, convey the sheet to one of the first cassette and the second cassette, based on a condition of the sheet determined from an image of the sheet generated from the reader reading the sheet at the second speed.

10. The apparatus according to claim **9**, wherein the erasing unit performs the erasing processing to erase the image by using heat.

11. The apparatus according to claim **9**, wherein the sheet conveying unit includes a first sheet conveying path that extends from the sheet supply unit toward the first position and a second sheet conveying path that branches from the first sheet conveying path at a first position downstream side of the reader and that merges with the first conveying path at a second position between the sheet supply unit and the reader.

12. The apparatus according to claim **11**, further comprising:

a separating unit arranged at the first position on the first conveying path and configured to switch a conveying path of the sheet between the first sheet conveying path and the second sheet conveying path.

13. The apparatus according to claim **9**, wherein the condition of the sheet read by the reader is a defect of the sheet.

14. The apparatus according to claim **9**, wherein the condition of the sheet read by the reader is an unevenness or a printing rate.

15. The apparatus according to claim **9**, further comprising a recording unit for making a mark at a predetermined position of the sheet according to the number of erasing times after erasing the image.

16. The apparatus according to claim **15**, wherein the mark made by the recording unit is a punch hole.

17. The apparatus according to claim **1**, wherein the sheet conveying unit includes a sheet conveying path formed in the shape of a loop.

18. The apparatus according to claim **9**, wherein the sheet conveying unit includes a sheet conveying path formed in the shape of a loop.
