(57) **ABSTRACT**

A lattice constant formatted epitaxial template for light emitting devices includes a starting epitaxial template having a base, a plurality of alternately arranged protrusions and depressions on the base; first material portions epitaxially formed on top of the protrusions and second material portions epitaxially formed in the depressions, wherein lattice constants of the first material portions on the protrusions are different from those of the second material portions in the depressions. A method for making a lattice constant formatted epitaxial template is provided. Also provided is a light emitting device containing a lattice constant formatted epitaxial template.

LATTICE-CONSTANT FORMATTED EPITAXIAL TEMPLATE FOR LIGHT EMITTING DEVICES AND A METHOD FOR MAKING THE SAME

FIELD OF THE INVENTION

The present invention relates in general to a lattice-constant formatted epitaxial template for semiconductor light emitters, more particularly for group III nitride compound semiconductor ultraviolet light or visible light emitters, a method of forming the same, and a light emitting device containing a lattice constant formatted epitaxial template.

DESCRIPTION OF THE RELATED ART

Nitride compound semiconductors such as InN, GaN, AlN, and their ternary and quaternary alloys are viewed as very important optoelectronic materials. Depending on alloy composition, nitride compounds can enable ultraviolet (UV) emissions ranging from 410 nm down to approximately 200 nm. This includes UVA (400-315 nm), UVB (315-280 nm), and part of UVC (280-200 nm) regimes. UVA emissions are leading to revolutions in curing industry, and UVB and UVC emissions owing to their germicidal effect are looking forward to general adoption in food, water, and surface disinfection businesses. Compared to the traditional UV light sources, such as mercury lamps, UV light emitters made of nitride compounds offer intrinsic merits. In general, nitride UV emitters are robust, compact, spectrum adjustable, and environmentally friendly. They offer high UV light intensity & dosage, which is ideal treatment for fresh food, water and surface storage, disinfection, and sterilization. Further, the light output can be modulated at frequencies up to a few hundreds of mega-hertz, promising them innovative light sources for covert communication and bio-chemical detection.

At the present, commercially available UVB and UVC light-emitting diodes (LEDs) commonly adopt the laminate structure containing a c-plane sapphire as UV transparent substrate, an AlN layer coated over the substrate serving as epitaxy template, and a set of AlN/AlGaN superlattice for dislocation and strain management. The utilization of AlN template and AlN/AlGaN superlattice enables the growth of high-quality high-conductivity n-type AlGaN electron supplier layer, which injects electrons into the following AlGaN-based multiple quantum well (MQW) active-region. On the other side of the MQW active-region are an AlGaN electron-blocking layer, an AlGaN hole injection layer, a hole supplier layer and a p-type GaN or InGaN layer for ohmic contact formation. The prior art AlGaN UV LED structures can be found in the reference. (e.g., "Milliwatt power deep ultraviolet light-emitting diodes over sapphire with emission at 278 nm", J. P. Zhang, et al, APPLIED PHYSICS LETTERS 81, 4910 (2002), the content of which is incorporated herein by reference in its entirety.).

Prior art UV LEDs suffer from low light output efficiency. Firstly, there is no lattice matched substrate for AlGaN based devices, which means strain management is essential for AlGaN device performance. When using UV transparent sapphire as substrate, an AlN template is inevitable. The AlN template is preferably to be thick, so as to maintain high structural quality. Thick AlN template or bulk AlN substrate exerts large biaxial compression on the overlying AlGaN based device structure, resulting in additional dislocation generation and surface roughness leading to inferior device

2

performance. When forming AlGaN based UV emitters on GaN substrate or template, the UV emitters experience strong biaxial tension from the larger GaN lattice constants. Biaxial tensile strain not only generates dislocations to deteriorate device internal quantum efficiency but also lead to surface cracks which are deadly device defects. In the past, AlN/AlGaN superlattice had been applied to manage strain for AlGaN heteroepitaxy over foreign substrates such as sapphire and GaN (e.g. "Crack-free thick AlGaN grown on sapphire using high temperature AlN/AlGaN superlattice for strain management", J. P. Zhang, et al, Appl. Phys. Lett. 80, 3542 (2002); "AlGaN layers grown on GaN using strain-relief interlayers", C. Q. Chen, et al, Appl. Phys. Lett. 81, 4961 (2002), and U.S. Pat. No. 7,547,925.). And pulsed source supply method was also investigated for high quality AlN and AlGaN epitaxial growth (e.g., U.S. Pat. No. 7,811, 847, and "Pulsed Atomic Layer Epitaxy of Ultrahigh-Quality $Al_xGa_{1-x}N$ structures for Deep Ultraviolet Emissions below 230 nm", J. P. Zhang et al, Appl. Phys. Lett. 81, 4392 (2002)). The other drawback of the prior art UV LEDs comes from light extraction, since the employment of UV absorbing p-GaN or p-InGaN contact layer and the large differences in the refractive indexes among air, sapphire, AlN, and AlGaN make light extraction out of the solid state device marginal, usually limiting light extraction efficiency to as small as 6%-10%.

The present invention discloses UV LED structures with greatly improved strain status and improved internal quantum and light extraction efficiencies and the method to form these UV LEDs.

SUMMARY OF THE INVENTION

One aspect of the present invention is directed to a light emitting device, which includes:

an n-type layer;

a p-type layer;

an active region sandwiched between the n-type layer and the p-type layer; and

a lattice constant formatted epitaxial template;

wherein the lattice constant formatted epitaxial template has a growing surface on which the n-type layer grows, and the growing surface has a plurality of first material portions and a plurality of second material portions with each of the first material portions being alternately arranged with each of the second material portions, and wherein lattice constants of the first material portions are different from those of the second material portions.

Another aspect of the present invention is directed to a lattice constant formatted epitaxial template, which includes:

a starting epitaxial template comprising a base, a plurality of alternately arranged protrusions and depressions on the base;

first material portions epitaxially formed on top of the protrusions and second material portions epitaxially formed in the depressions, wherein lattice constants of the first material portions on the protrusions are different from those of the second material portions in the depressions.

Another aspect of the present invention is directed to a light emitting device, which includes:

an n-type layer;

a p-type layer;

an active region sandwiched between the n-type layer and the p-type layer;

wherein the n-type layer contains alternatively arranged first portions and second portions, and lattice constants of the first portions are smaller than lattice constants of the second portions.

Another aspect of the present invention is directed to a light emitting device, which includes:

a p-type layer;

a light emitting active region; and

the above described lattice constant formatted epitaxial template;

wherein the active region is directly formed on the first material portions and the second material portions of the lattice constant formatted epitaxial template.

Another aspect of the present invention is directed to a method of making a lattice constant formatted epitaxial template, which includes:

providing a starting epitaxial template having a plurality of alternately arranged protrusions and depressions;

simultaneously and epitaxially growing first material portions on the protrusions and second material portions in the depressions from the same feed material containing at least two elements with different surface diffusion lengths, wherein composition segregation occurs between the first material portions and the second material portions due to the difference in the surface diffusion lengths of the at least two elements and the dimensions of the protrusions and the depressions.

The method may further include:

providing an epitaxial template substrate; and

forming, via a nanoimprint or photolithography and etch process, the protrusions and the depressions on the epitaxial template substrate to obtain the starting epitaxial template, wherein the protrusions have a lateral dimension of 100-3000 nm, a height of 200-5000 nm, and a pitch of 200-3500 nm.

In the above method, the first material portions and the second material portions are made of AlGaN via the feed material including trimethylaluminium (TMA), trimethylgallium (TMG), and ammonia.

The method may further include:

forming an n-type layer on the first and second material portions;

forming an active region over the n-type layer; and

forming a p-type layer over the active region.

The method may further include removing the starting epitaxial template, the first material portions and the second material portions so as to expose the n-type layer.

BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings, which are included to provide a further understanding of the invention and constitute a part of this application, illustrate embodiments of the invention and together with the description serve to explain the principle of the invention. Like reference numbers in the figures refer to like elements throughout, and a layer can refer to a group of layers associated with the same function.

FIG. 1 illustrates the cross sectional schematic drawing of a starting epitaxial template according to an embodiment of the present invention.

FIG. 2A illustrates a close packed hexagonal pattern for two-dimensional periodic arrangement of protrusions of the starting epitaxial template shown in FIG. 1.

FIG. 2B illustrates a square pattern for two-dimensional periodic arrangement of protrusions of the starting epitaxial template shown in FIG. 1.

FIG. 2C illustrates a stripe pattern for one-dimensional periodic arrangement of protrusions of the starting epitaxial template shown in FIG. 1.

FIG. 3 illustrates a generalized schematic diagram of a heteroepitaxial structure.

FIG. 4 illustrates a part of a starting epitaxial template to highlight AlGaN epitaxy process on the starting epitaxial template according to an embodiment of the present invention.

FIG. 5 illustrates an in-plane compositionally formatted thus lattice constant formatted epitaxial template according to an embodiment of the present invention.

FIG. 6 illustrates an in-plane compositionally formatted thus lattice constant formatted epitaxial template according to another embodiment of the present invention.

FIG. 7 illustrates an n-type layer, such as an AlGaN layer, epitaxially formed over a lattice constant formatted epitaxial template according to an embodiment of the present invention.

FIG. 8 illustrates a laminate structure of a light emitter, such as a UV light emitter, according to an embodiment of the present invention, formed over a lattice constant formatted epitaxial template.

FIG. 9 illustrates a laminate structure of a light emitter, such as a UV light emitter, according to an embodiment of the present invention, formed over a lattice constant formatted epitaxial template.

FIG. 10 illustrates the laminate structure of a thin-film UV light emitter according to an embodiment of the present invention, in which the lattice constant formatted epitaxial template is removed upon device fabrication.

FIG. 11 illustrates a laminate structure of a light emitter, such as a visible light emitter, according to an embodiment of the present invention, formed over a lattice constant formatted epitaxial template.

DETAILED DESCRIPTION OF EMBODIMENTS

The present invention discloses a lattice constant formatted epitaxial template for a light emitting device with improved internal quantum and light extraction efficiencies. Throughout the specification, the term III-nitride or nitride in general refers to metal nitride with cations selecting from group MA of the periodic table of the elements. That is to say, III-nitride includes MN, GaN, InN and their ternary (AlGaN, InGaN, InAlN) and quaternary (AlInGaN) alloys. In this specification, a quaternary can be reduced to a ternary for simplicity if one of the group III elements is significantly small. For example, if the In-composition in a quaternary AlInGaN is significantly small, smaller than 1%, then this AlInGaN quaternary can be shown as ternary AlGaN for simplicity. Using the same logic, a ternary can be reduced to a binary for simplicity if one of the group III elements is significantly small. For example, if the In-composition in a ternary InGaN is significantly small, smaller than 1%, then this InGaN ternary can be shown as binary GaN for simplicity. III-nitride or nitride can also include small compositions of transition metal nitride such as TiN, ZrN, HfN with molar fraction not larger than 10%. For example, III-nitride or nitride may include $Al_xIn_yGa_zTi_{(1-x-y-z)}N$, $Al_xIn_yGa_zZr_{(1-x-y-z)}N$, $Al_xIn_yGa_zHf_{(1-x-y-z)}N$, with $(1-x-y-z) \leq 10\%$. A III-nitride layer or active-region means that the layer or active-region is made of III-nitride semiconductors.

In the following contents, wurtzite c-plane nitride light-emitting devices or structures are used as embodiments to elucidate the principle and spirit of the present invention. Those of ordinary skills in the field can apply the teachings

in this specification and given by the following embodiments to non-c-plane nitride semiconductors, II-VI semiconductors and other lattice-mismatched light-emitting devices or semiconductor devices without creative work.

Illustrated in FIG. **1** is the cross sectional schematic drawing of a starting epitaxial template **20'** according to an embodiment of the present invention. Starting epitaxial template **20'** includes a base **21'**, a set of upwardly pointing protrusions **22'**, which sit on one surface of base **21'** and are separated from each other by depressions **23'**. The in-plane arrangement of protrusions **22'** can take any two-dimensional or one-dimensional patterns. For example, protrusions **22'** can be stripes lying on one surface of base **21'**, as shown in FIG. **2C** in bird's eye view. Preferably, protrusions **22'** are arranged on base **21'** periodically, possessing repeating unit cell and pitch L. Here, pitch L is defined as the sum of lateral dimension of a protrusion **22'** and the distance in the same lateral direction between the protrusion and its nearest neighboring protrusion. Refer to FIG. **2C** and FIG. **1**, protrusions **22'** are parallel stripes with a lateral dimension D and a height H, and are spaced from each other by a distance of pitch L minus lateral dimension D. FIG. **2A**, and FIG. **2B** illustrate two cases of two-dimensional periodic arrangement of protrusions **22'** within the surface of base **21'**. In FIG. **2A**, protrusions are arranged in close packed hexagonal pattern, with in-plane pitches L, and lateral dimension D, whereas in FIG. **2B** the arrangement pattern changes into square pattern. Refer to FIGS. **1**, **2A** and **2B**, protrusions **22'** are circular pillars sitting on base **21'**. Protrusions **22'** can also be pillars with other shape, such as hexagon, triangle, or other regular or irregular shape. While protrusion **22'** may occupy one surface of base **21'** via one-dimensional or two-dimensional periodic patterns, they may also be arranged on the surface of base **21'** randomly.

According to an embodiment of the present invention, starting epitaxial template **20'** is intended for high-quality AlGaN layer epitaxy (ternary AlGaN or with a trace amount of Indium as previously explained). Hence starting epitaxial template **20'** is preferably made of materials suitable for AlGaN epitaxy, such as crystal sapphire, AlN, SiC, GaN, AlGaN, Si et al. Starting epitaxial template **20'** can be a self supporting substrate made of the abovementioned materials, or can be a thin film made of the abovementioned materials formed over a supporting substrate (though for simplicity the substrate is not explicitly shown in FIG. **1**). Further, the parameters D, H, and L are selected to assure good epitaxy process for a nitride layer such as AlGaN layer. The ranges of these parameters are set as follows: lateral dimension D: 100-3000 nm, height H: 200-1500 nm, pitch L: 200-3500 nm. The following discussion lays out the physics behind the parameter selections.

It is well known to the field of interest that there is no lattice matched substrate for AlGaN based UV light emitters. So, AlGaN based UV devices have to be heteroepitaxially formed over foreign substrate or template. Shown in FIG. **3** is a generalized schematic diagram illustrating a heteroepitaxial structure, containing a substrate **S1** with free in-plane lattice constant a_0 and an epilayer **E1** with free in-plane lattice constant a. Presumably, substrate **S1** is of substantially thick thickness and epilayer **E1** of substantially thin thickness, so that strain energy can be viewed as only exerted within epilayer **E1**. That is to say, substrate **S1** will maintain its free lattice constant and epilayer **E1** will deform its lattice constant to comply with the epitaxial growth relationship. The unit strain energy, i.e., the strain energy per

unit volume for a wurtzite (0001) plane heteroepitaxial structure is (Reference: J. Shen et al, J. Crystal Growth, 240, 6, (2002).),

$$U = \frac{1}{s_{11} + s_{12}} \varepsilon^2 = \frac{1}{s_{11} + s_{12}} \left(\frac{a - a_0}{a_0} \right)^2$$

where s_{jj} are the elastic compliance coefficients of epilayer **E1**, and the strain ϵ is,

$$\varepsilon = \frac{a - a_0}{a_0}$$

So, the total strain energy within epilayer **E1** is,

$$E_{str} = U \times A \times t$$

where A, t are the area and thickness of epilayer **E1**, respectively. As seen, the total strain energy is proportional to epilayer's area and thickness. The strain energy gets larger as the epilayer gets thicker. If it is larger than the dislocation formation energy, dislocations will be generated within epilayer **E1**; if it is tensile strain and larger than the crack formation energy, cracks will be generated within epilayer **E1**. Generally speaking, crack formation energy is much higher than dislocation formation energy. The total strain energy equation tells that to achieve high-quality epilayer with thick thickness without dislocation or crack generation, a promising approach is to limit the epilayer area thus limiting the strain energy.

FIG. **4** illustrates a part of a starting epitaxial template **20'** to highlight AlGaN epitaxy process on the starting epitaxial template. Gallium and Indium adatoms are generally more mobile than Aluminum adatoms. Under optimal AlGaN epitaxial growth conditions (e.g., growth temperature 1050-1120° C., pressure 40-100 torr, V/III ratio 500-3000), Ga adatoms possess diffusion length at least 100 times larger than that of Al adatoms. In literature there are reports that Ga adatoms diffusion length on (0001) GaN surface can be in-between 6 to 24 microns, whereas Al adatoms only possess diffusion length less than 100 nm even at more elevated growth temperatures. As a result, Al adatoms (black dots shown in FIG. **4**) basically sticks to wherever they land on the growing surface, and Ga adatoms (circles in FIG. **4**) move around to find their most energetically favorable lattice sites, which are usually available in the surface dent, step or kink area. That is to say, making certain surface features can result in segregation of less mobile and highly mobile adatoms, directly leading to composition segregation in the epilayer so formed. Long diffusion length of Ga adatom can also result in desorption from the growing surface. When performing AlGaN epitaxial growth on starting epitaxial template **20'**, because of Ga adatoms' desorption, besides their diffusion into and trap within depressions **23'**, the epilayers on top of protrusion **22'** (i.e., material portions **22** or portions **22** in FIGS. **5-7**) are highly Al-rich AlGaN layers, hence with smaller lattice constants, whereas the epilayers within depressions **23'** (i.e., material portions **23** or portions **23** in FIGS. **5-7**) are Ga-rich AlGaN layers, hence with larger lattice constants. Also, the growth rate in the depressions **23'** will be higher than that on protrusions **22'**, eventually leading to planarization of starting epitaxial template **20'** and resulting in an in-plane compositionally formatted thus lattice constant formatted epitaxial template **20A**, as shown in FIG. **5**. To have high Al-composition

7

contrast between portions **22** and **23** in FIG. **5**, the parameters D, H, and L of starting epitaxial template **20'** have to be selected to enhance Ga adatoms surface diffusion. For this purpose, the parameters are set to be within the range: lateral dimension D: 100-3000 nm, height H: 200-1500 nm, pitch L: 200-3500 nm, more preferably to be within the range: lateral dimension D: 100-1000 nm, height H: 200-1000 nm, pitch L: 200-1500 nm Under certain circumstances, the Al-compositions of portions **22** and **23** can be predicted. When growth conditions allowing Al and Ga incorporation efficiencies (defined as the efficiency of gaseous phase Al or Ga atoms incorporating into solid phase Al or Ga atoms) to be equal, and the lateral dimension D of protrusion **22'** is much larger than the Al adatom surface diffusion length but much smaller than the Ga adatom surface diffusion length, then the Al compositions of portions **22** and **23** depend on the surface area ratio of protrusions **22'** and depressions **23'**. For example, under the above specified conditions, if the Al/Ga molar flow ratio in the gaseous phase is 1, and the surface ratio of protrusions **22'** to depressions **23'** equals to 1, then the Al-compositions of portions **22** and **23** will be predicted to be substantially around 100% and 33%, respectively.

The lattices of portions **22** and **23** are preferably to be relaxed or partly relaxed, via misfit dislocation generation at the interfaces between portions **22** and protrusions **22'**, and between portions **23** and base **21'**, respectively. The threading dislocations associated with the above mentioned misfit dislocations are provided with termination sites along the sidewalls of protrusions **22'** and portions **22** and **23**. To further facilitate threading dislocation termination to the sidewalls, dislocation bending structure such as an AlN inserting layer, or a set of AlN/AlGaN superlattice or multiple layers is formed on starting epitaxial template **20'**, as shown in FIG. **6**. The dislocation bending structures are marked as layer **222** and **221** on top of protrusions **22'** and base **21'**, respectively. If the dislocation bending structure (**222**, **221**) is an AlN insertion layer, its thickness is preferably in-between 5-50 nm. In case the dislocation bending structure is AlN/AlGaN superlattice, the superlattice period can be 5-20 pairs, with individual AlN and AlGaN thickness to be 2-10 nm, and 10-200 nm, respectively, whereas the composition of the AlGaN layers within the superlattice can nominally be the same as those of portions **22** and **23**, respectively.

Lattice constant formatted templates **20A** and **20B** as shown in FIG. **5** and FIG. **6** inherit the high structural quality of starting epitaxial template **20'**, yet with in-plane formatted composition and the resultant formatted lattice constants. When using template **20A** or **20B** for AlGaN based UV light emitters, the strain status will be fundamentally different from that of the prior art UV light emitters. In the prior art UV light emitters, for those formed over AlN template or bulk AlN substrate, the whole UV light emitters will be under biaxially compressive strain, which causes dislocation generation and epitaxial three-dimensional growth, resulting in rough surface and inferior device performance. The strain exerted to AlGaN epilayer grown on bulk AlN is within 0%-2.51% depending on Al-composition of AlGaN layer. Meanwhile, for AlGaN based UV emitters formed over GaN template or substrate, the whole device structure will be under biaxially tensile strain of −2.45%-0%, depending on Al-composition. This tensile strain tends to generate cracks within the UV emitters. To summarize, strain within the prior art UV emitters maintains the same sign for the whole

8

epitaxial area, as a result, the device performance is very vulnerable to strain as strain energy is proportional to strained area.

Since templates **20A** and **20B** shown in FIG. **5** and FIG. **6** possess formatted lattice constants, they can locally biaxially exert different type of strains to films formed over them. For example, referring to FIG. **7**, an n-type AlGaN layer **30** is epitaxially formed on template **20B**, with Al-composition being lower than that of portions **22** yet higher than that of portions **23**. As such, portions **22** and **23** will exert biaxially compressive and tensile strain, respectively to the layer portions epitaxially formed on them. That is to say, layer portions **30A** grown on top of portions **22** and layer portions **30B** grown on top of portions **23** are under biaxially compressive and tensile strain, respectively. N-type AlGaN layer **30** thus contains alternatively arranged in-plane tensile and compressive portions (**30A** and **30B**), wherein the tensile portions (**30B**) are of larger in-plane lattice constants as compared to the compressive portions (**30A**), even though the tensile and compressive portions are of the same compositions. Templates **20A** and **20B** thus break down the otherwise large-area substantially uniform strain into numerous opposite-sign strains spaced by each other. Since each individual portions **30A** and **30B** of layer **30** has very limited area (defined by parameter D and pitch L), layer **30** can coherently grow up to a greater thickness on template **20A** or **20B** without defect especially crack generation thanks to the reduced strain energy and sidewalls for threading dislocation termination. In some embodiments, layer **30** can coherently grow on template **20A** or **20B** up to more than 2 μm without lattice relaxation. In other embodiments, when the layer thickness is substantially thick, for example, more than 4 μm, layer **30** can be partly relaxed on the surface portion away from template **20A** or **20B**. Still in other embodiments, when the layer thickness is substantially thick, for example, more than 6 μm, layer **30** can be fully relaxed on the surface portion away from template **20A** or **20B**, with the surface portion close to template **20A** or **20B** still being strained. Coherent or partly relaxed layer **30** can transfer its formatted in-plane lattice constant to the following thin film, such as a light emitting layer or MQW structure, grown on layer **30**.

According to some embodiments of the present invention, starting epitaxial template **20'** is made of AlN. It can be a bulk AlN substrate, or can be an AlN thin film with thickness preferably greater than 2 μm, formed over another substrate such as sapphire, SiC, or Si. The protrusions **22'** are made of AlN, arranged over the base **21'** also being AlN, according to the patterns shown in FIGS. **2A**-**2C**. The parameters D, H, and L are respectively selected to be 200, 1000, and 500 nm in this embodiment. The protrusions **22'** and depressions **23'** of template **20'** according to this embodiment are formed via nanoimprint process, which is a commercially available technique used in nano-fabrication. Reference of the nanoimprint process can be found in U.S. Pat. No. 7,419,764 which is herein incorporated by reference in its entirety. The so-formed template **20'** is loaded into an metalorganic chemical vapor deposition (MOCVD) reactor, heated up to a temperature of 1100° C. under hydrogen and ammonia ambient, for the formation of lattice-constant formatted template **20A**. The formation starts with the simultaneously supply of Al, Ga, and N sources, which can respectively be trimethylaluminium (TMA), trimethylgallium (TMG), and ammonia. The molar flow ratio of TMA and TMG sources are selected to get the desired Al-compositions for the portions **22** and **23**, which are different because of the engineered surface structure of template **20'** and the large

difference in surface diffusion lengths of Al and Ga adatoms, as previously explained. In some embodiments, the molar flow ratio of TMA and TMG sources are selected close to be 1. This will result in an Al-composition greater than 50% for the portions **22**, and an Al-composition less than 50% for the portions **23**. In some embodiments, the resultant Al-compositions of portions **22** and **23** can be respectively 60% and 45%. In some embodiments, the resultant Al-compositions of portions **22** and **23** can be respectively 70% and 40%. In some embodiments, the resultant Al-compositions of portions **22** and **23** can be respectively 90% and 35%. In some embodiments, the resultant Al-compositions of portions **22** and **23** can be respectively 97% and 48%. The composition difference between portion **22** and **23** is governed by growth temperature and the parameters D, H, and L. It also slightly depends on ammonia flow rate. Upon formation going on, the height difference between portions **22** and **23** will reduce since the growth rate is higher for portions **23**. The Al-composition difference between portions **22** and **23** will rather abruptly vanish as the portions' height difference is less than 100 nm in some cases, or less than 50 nm in other cases. Upon achieving this height difference of portions **22** and **23**, the planarization is completed, and lattice constant formatted template **20**A is achieved, and can be used for the following UV emitter epitaxial formation. In the prior art, UV light emitters formed over bulk AlN substrate or AlN thin film template are under large area constant biaxial compression, leading to dislocation generation and surface roughness. According to the present invention, using the achieved template **20**A for AlGaN based UV emitters can result in micron or submicron area scale in-plane strain sign flip and strength modulation, leading to improved material quality and device internal quantum efficiency.

The laminate structure of a UV light emitter according to one embodiment of the present invention is illustrated in FIG. **8**, where the lattice constant formatted template **20**A, or **20**B is employed, and is optionally formed upon a substrate **10** (note that in the case that starting epitaxial template **20'** is made of a bulk AlN substrate, substrate **10** in FIG. **8** and FIG. **9** is omitted). Substrate **10** can be selected from sapphire, SiC, Si, and the like. Template **20**A, or **20**B is made of AlN with AlGaN in-plane composition formatted portions **22** and **23** according FIG. **5** or FIG. **6**. Coherently lying on template **20**A or **20**B is an n-AlGaN layer **30**, which is under micron or submicron scale in-plane strain sign flip and strength modulation, as is revealed in FIG. **7**. As layer **30** is conformally formed on template **20**A or **20**B, the surface of layer **30** in contact with template **20**A or **20**B has first portions formed on portions **22** and second portions formed on portions **23**, and there may be a difference in height between the first portions and the second portions corresponding to the height difference between portions **22** and portions **23**. Layer or film **30** experiencing the in-plane strain modulation maintains high structural quality and electrical conductance, ensuring the following UV light emitting AlGaN based MQW **40** of high internal quantum efficiency, because of the reduced defect density and enhanced electron spreading for uniform electron injection into MQW **40**. Formed over MQW **40** is p-type AlGaN layer **50**, comprising a p-type electron blocking layer, a hole injection layer, and a hole supplier layer. On top of p-AlGaN layer **50** is a p-type contact layer **60**, which can be a p-type GaN or InGaN layer for ohmic contact formation. The UV emitter structure shown in FIG. **8** can be fabricated into a UV light emitting device as shown in FIG. **9**, where n- and p-electrical contacts (**81**, **82**) are formed via standard chip fabrication process. The embodiment shown in FIG. **9** can

emit UV light either through the substrate **10** (surface emitting device) or along the plane of MQW **40** (side emitting device).

According to some other embodiments of the present invention, starting epitaxial template **20'** is made of GaN. It can be a bulk GaN substrate, or can be a GaN thin film with thickness preferably greater than 4 μm, formed over another substrate such as sapphire, SiC, or Si. The protrusions **22'** are made of GaN, arranged over the base **21'** also being GaN, according to the patterns shown in FIGS. **2A-2C**. The parameters D, H, and L are respectively selected to be 300, 1500, and 600 nm in this embodiment. The patterns of template **20'** according to this embodiment are formed via nanoimprint process, which is a commercially available technique used in nano-fabrication. Reference of the nanoimprint process can be found in U.S. Pat. No. 7,419, 764. The so-formed template **20'** is loaded into an metalorganic chemical vapor deposition (MOCVD) reactor, heated up to a temperature of 1100° C. under hydrogen and ammonia ambient, for the formation of lattice-constant formatted template **20**A or **20**B. The formation starts with the simultaneously supply of Al, Ga, and N sources, which can respectively be trimethylaluminium (TMA), trimethylgallium (TMG), and ammonia. The molar flow ratio of TMA and TMG sources are selected to get the desired Al-compositions for the portions **22** and **23**, which are different because of the engineered surface structure of template **20'** and the large difference in surface diffusion lengths of Al and Ga adatoms, as previously explained. In some embodiments, the molar flow ratio of TMA and TMG sources are selected close to be 0.9. This will result in an Al-composition greater than 50% for the portions **22**, and an Al-composition less than 50% for the portions **23**. In some embodiments, the resultant Al-compositions of portions **22** and **23** can be respectively 60% and 45%. In some embodiments, the resultant Al-compositions of portions **22** and **23** can be respectively 70% and 40%. In some embodiments, the resultant Al-compositions of portions **22** and **23** can be respectively 90% and 35%. In some embodiments, the resultant Al-compositions of portions **22** and **23** can be respectively 98% and 48%. The composition difference between portion **22** and **23** is governed by growth temperature and the parameters D, H, and L. It also slightly depends on ammonia flow rate. Upon formation going on, the height difference between portions **22** and **23** will reduce since the growth rate is higher for portions **23**. The Al-composition difference between portions **22** and **23** will rather abruptly vanish as the portions' height difference is less than 100 nm in some cases, or less than 50 nm in other cases. Upon achieving this height difference of portions **22** and **23**, the planarization is completed, and lattice constant formatted template **20**A or **20**B is achieved, and can be used for the following UV emitter epitaxial formation. In the prior art, UV light emitters formed over bulk GaN substrate or GaN film template are under large area constant biaxial tension, leading to dislocation generation and surface crack. According to the present invention, using the achieved template **20**A or **20**B for AlGaN based UV emitters can result in micron or submicron scale in-plane strain sign flip and strength modulation, leading to improved material quality and device internal quantum efficiency.

The laminate structure of a UV light emitter according to an embodiment of the present invention is illustrated in FIG. **8**, where the lattice constant formatted template **20**A, or **20**B is employed, and is optionally formed upon a substrate **10** (note that in the case that starting epitaxial template **20'** is made of a bulk GaN substrate, substrate **10** in FIG. **8** and

FIG. **9** is omitted). Substrate **10** can be selected from sapphire, SiC, Si, and the like. Template **20**A, or **20**B is made of GaN with AlGaN in-plane composition formatted portions **22** and **23** according FIG. **5** or FIG. **6**. Coherently lying over template **20**A or **20**B is an n-AlGaN layer **30**, which is under micron or submicron scale in-plane strain modulation, as is revealed in FIG. **7**. Layer or film **30** experiencing the in-plane strain modulation maintains high structural quality and electrical conductance, ensuring the following UV light emitting AlGaN based MQW **40** of high internal quantum efficiency, because of the reduced defect density and enhanced electron spreading for uniform electron injection into MQW **40**. Formed over MQW **40** is p-type AlGaN layer **50**, comprising a p-type electron blocking layer, a hole injection layer, and a hole supplier layer. On top of p-AlGaN layer **50** is a p-type contact layer **60**, which can be a p-type GaN or InGaN layer for ohmic contact formation. Also notice that in FIG. **9** and FIG. **10**, to further force current uniform spreading, a lightly doped n⁻-AlGaN of higher vertical resistance is employed in-between MQW **40** and n-AlGaN **30**. The UV emitter structure shown in FIG. **8** can be made into UV light emitting devices. As shown in FIG. **9**, n- and p-electrical contacts (**81**, **82**) are formed via standard chip fabrication process. The embodiment shown in FIG. **9** according to this aspect of the present invention can emit UV light along the plane of MQW **40** (side emitting device), i.e., super luminescence light emitting diode or UV laser diode can be fabricated according to this embodiment of the present invention.

Further, for the UV emitter structure shown in FIG. **8**, the UV light absorbing template **20**A or **20**B mostly made of GaN according to this aspect of the present invention can be removed, to make a surface emitting UV LED, as shown in FIG. **10**. First a conductive UV light reflector **65** is formed over p-contact layer **60**. Then the structure is attached to a superstrate **70** for mechanical support. Superstrate **70** is either electrical conductive or possesses electrical conductive vias, so that p-contact **82** can be formed over superstrate **70**. As shown in FIG. **10**, lattice constant formatted template **20**A, or **20**B plus its substrate if any is removed, and n-contact **81** is formed over n-AlGaN layer **30**. Since in this aspect of the invention, template **20**A or **20**B is made mostly of GaN, the removal of it can be readily achieved via laser liftoff process, which is a standard blue LED process at the present. Upon the removal of template **20**A or **20**B, the exposed surface of n-AlGaN layer **30** can be roughened to enhance UV light extraction through n-AlGaN layer **30**. UV LEDs made according to this aspect of the present invention possess both high internal quantum efficiency and high light extraction efficiency.

According to still other embodiments of the present invention, starting epitaxial template **20'** is made of sapphire, Si, or SiC substrate. In an exemplary embodiment according to this aspect of the present invention, starting epitaxial template **20'** is made of sapphire substrate. The protrusions **22'** are made of sapphire, arranged over the base **21'** also being sapphire, according to the patterns shown in FIGS. 2A-2C. The parameters D, H, and L are respectively selected to be approximately 1500, 1500, and 3000 nm in this embodiment. The protrusions **22'** and depressions **23'** of template **20'** according to this embodiment are formed via standard semiconductor fabrication process including photolithography and etching. The so-formed template **20'** is loaded into an metalorganic chemical vapor deposition (MOCVD) reactor, heated up to a temperature of 1030° C. under hydrogen ambient for surface cleaning. Then at lower temperatures of 520-750° C. an MN layer of 20-100 nm

thick is formed over template **20'** before being heated up to higher temperatures of 1050-1150° C. for the formation of lattice-constant formatted template **20**A. Template **20**A formation starts with the simultaneously supply of Al, Ga, and N sources, which can respectively be trimethylaluminium (TMA), trimethylgallium (TMG), and ammonia. The molar flow ratio of TMA and TMG sources are selected to get the desired Al-compositions for the portions **22** and **23**, which are different because of the engineered surface structure of template **20'** and the large difference in surface diffusion lengths of Al and Ga adatoms, as previously explained. In some embodiments, the molar flow ratio of TMA and TMG sources are selected close to be 1. This will result in an Al-composition greater than 50% for the portions **22**, and an Al-composition less than 50% for the portions **23**. In some embodiments, the resultant Al-compositions of portions **22** and **23** can be respectively 60% and 45%. In some embodiments, the resultant Al-compositions of portions **22** and **23** can be respectively 70% and 40%. In some embodiments, the resultant Al-compositions of portions **22** and **23** can be respectively 90% and 35%. In some embodiments, the resultant Al-compositions of portions **22** and **23** can be respectively 97% and 48%. The composition difference between portion **22** and **23** is governed by growth temperature and the parameters D, H, and L. It also slightly depends on ammonia flow rate. Upon formation going on, the height difference between portions **22** and **23** will reduce since the growth rate is higher for portions **23**. The Al-composition difference between portions **22** and **23** will rather abruptly vanish as the portions' height difference is less than 100 nm in some cases, or less than 50 nm in other cases. Upon achieving this height difference of portions **22** and **23**, the planarization is completed, and lattice constant formatted template **20**A is achieved, and can be used for the following UV emitter epitaxial formation. The UV light emitter epitaxial and device structures can be the same as shown in FIG. **8** and FIG. **9**, but with the absence of substrate **10** shown there.

The embodiments disclosed above take AlGaN lattice constant formatted epitaxial templates and UV light emitters as example. However, the present invention is not limited to AlGaN lattice constant formatted epitaxial templates and UV light emitters. Similarly, InGaN materials (or AlInGaN materials) are suitable for making lattice constant formatted epitaxial template for InGaN thin film epitaxy, in view of the large difference in surface diffusion lengths of In and Ga adatoms under optimal InGaN growth conditions. The optimal InGaN epitaxial growth conditions include high growth pressure of 200-760 torr, lower growth temperatures of 600-850° C., and high V/III ratio of 2000-30000. Under the optimal InGaN growth conditions, Al and Ga adatoms possess small even vanishing surface diffusion lengths, as compared to that of In adatoms. When performing InGaN or AlInGaN epitaxial growth on a starting epitaxial template **20'** under the optimal InGaN growth conditions, material portions **22** formed on protrusion **22'** will be In-deficient and have smaller lattice constants as compared to material portions **23** formed in depressions **23'**. InGaN or AlInGaN lattice constant formatted epitaxial templates are ideal for high-In-content InGaN epitaxy for green, amber and red InGaN light emitters.

According to this aspect of the present invention, starting epitaxial template **20'** is made of GaN. It can be a bulk GaN substrate, or can be a GaN thin film with thickness preferably greater than 4 μm, formed over another substrate such as sapphire, SiC, or Si. The protrusions **22'** are made of GaN, arranged over the base **21'** also being GaN, according to the

patterns shown in FIGS. 2A-2C or other suitable patterns. The parameters D, H, and L are selected to be 100-3000 nm, 200-1500 nm, and 200-3500 nm, respectively, more preferably to be 100-1000 nm, 200-1000 nm, and 200-1500 nm, respectively. The parameters D, H, and L are 300, 300, and 600 nm, respectively, in this embodiment. The patterns of template **20'** according to this embodiment are formed via nanoimprint process, which is a commercially available technique used in nano-fabrication. Reference of the nanoimprint process can be found in U.S. Pat. No. 7,419, 764. The so-formed template **20'** is loaded into an metalorganic chemical vapor deposition (MOCVD) reactor, heated up to a temperature of 720-850° C. under nitrogen and ammonia ambient to meet the optimal InGaN epitaxial growth conditions for the formation of lattice-constant formatted template **20A**. The formation starts with simultaneously supply of In, Ga, and N sources, which can respectively be trimethylindium (TMI), trimethylgallium (TMG), and ammonia. The molar flow ratio of TMI and TMG sources and the formation temperature are selected to get the desired In-compositions for the portions **22** and **23**, which are different because of the engineered surface structure of template **20'** and the large difference in surface diffusion lengths of In and Ga adatoms, as previously explained. In some embodiments, the molar flow ratio of TMI and TMG sources are selected close to be 2.0, and the formation temperature is selected to be 800° C. This will result in an In-composition greater than 8% for the portions **23**, and an In-composition less than 3% for the portions **22**. In some embodiments, the resultant In-compositions of portions **22** and **23** can be respectively 1.0% and 13%. In some embodiments, the resultant In-compositions of portions **22** and **23** can be respectively 2.5% and 10%. In some embodiments, the resultant In-compositions of portions **22** and **23** can be respectively 2% and 12%. In some embodiments, the resultant Al-compositions of portions **22** and **23** can be respectively 3% and 9%. The composition difference between portion **22** and **23** is governed by growth temperature and the parameters D, H, and L. It also slightly depends on ammonia flow rate. Upon formation going on, the height difference between portions **22** and **23** will reduce since the growth rate is higher for portions **23**. The In-composition difference between portions **22** and **23** will rather abruptly vanish as the portions' height difference is less than 50 nm in some cases, or less than 20 nm in other cases. Upon achieving this height difference of portions **22** and **23**, the planarization is completed, and lattice constant formatted epitaxial template **20A** is achieved, and can be used for the following InGaN visible light emitter epitaxial formation. In the prior art, InGaN visible light emitting MQW formed over bulk GaN substrate or GaN film template are under large area constant biaxial compression, leading to dislocation generation and large piezoelectric polarization. According to the present invention, using the achieved template **20A** for InGaN MQW based visible light emitters can result in micron or submicron scale in-plane strain sign flip and strength modulation, leading to improved material quality and device internal quantum efficiency.

The laminate structure of a visible light emitter according to an embodiment of the present invention is illustrated in FIG. **11**, where an InGaN lattice constant formatted epitaxial template **20A** is employed, and is optionally formed upon a substrate **10** (note that in the case that starting epitaxial template **20'** is made of a bulk GaN substrate, substrate **10** in FIG. **11** is omitted). Substrate **10** can be selected from sapphire, SiC, Si, and the like. Template **20A** is made of GaN with InGaN in-plane composition formatted portions **22** and

23 according FIG. **5**. Coherently formed on template **20A** can be a n-type layer **30** made of InGaN material (not shown in FIG. **11**), or directly coherently lying on template **20A** is an InGaN based MQW such as an InGaN/InGaN or GaN/InGaN MQW **40**, which is under micron or submicron scale in-plane strain modulation, because of the different In-compositions of portions **22** and **23** as shown in FIG. **5**. InGaN MQW **40** experiencing the in-plane strain modulation maintains high structural quality and suffers from less strain, ensuring high internal quantum efficiency and reduced forward turn on voltage because of the reduced defect density and piezoelectric polarization. Formed over MQW **40** is p-type AlGaN layer **50**. On top of p-AlGaN layer **50** is a p-type contact layer **60**, which can be a p-type GaN or InGaN layer for ohmic contact formation. Finally, a transparent conductive layer (TCL) **70**, such as an indium tin oxide (ITO) layer is formed over layer **60** for current spreading and light extraction.

When the active region is directly formed on an InGaN or AlGaN lattice constant formatted epitaxial template, material portions **22** and **23** of lattice constant formatted epitaxial template **20A** or **20B** may function as n-type layer and, for that purpose, material portions **22** and **23** can be properly doped.

The principal of the present invention can be readily extended to other semiconductor devices as long as there is strain to mediate. According to the teachings taught above, using a lattice constant formatted epitaxial template can split the otherwise large-area, substantially uniform, biaxially compressive or tensile strain into numerous miniature areas of strains with reduced and opposite-signed strains. The general steps to form a lattice constant formatted epitaxial template consist:

Identifying a starting epitaxial template material and an epitaxial material that can be epitaxially formed over the template material, whereas the epitaxial material shall contain at least two different elements which possess substantially different diffusion lengths when performing epitaxial growth of the epitaxial material on the epitaxial template;

Forming protrusions and depressions on the epitaxial template material to make a starting epitaxial template. The dimensions of the protrusions and depressions shall take the advantage of the different diffusion lengths of the at least two different elements of the epitaxial material, to make the epitaxially formed materials on top of the protrusions and depressions have different compositions thus different lattice constants.

Performing epitaxial growth on the starting epitaxial template. The growth conditions shall facilitate the composition segregation due to the difference of the at least two different elements' surface diffusion lengths. The lattice constant formatted template will be accomplished as the starting epitaxial template approaches surface planarization.

The present invention has been described using exemplary embodiments. However, it is to be understood that the scope of the present invention is not limited to the disclosed embodiments. On the contrary, it is intended to cover various modifications and similar arrangement or equivalents which can be obtained by a person skilled in the art without creative work or undue experimentation. The scope of the claims, therefore, should be accorded the broadest interpretation so as to encompass all such modifications and similar arrangements and equivalents.

What is claimed is:

1. A light emitting device comprising:
   an n-type layer;
   a p-type layer;

an active region sandwiched between the n-type layer and the p-type layer; and

a lattice constant formatted epitaxial template;

wherein the lattice constant formatted epitaxial template has a growing surface on which the n-type layer grows, and the growing surface comprises a plurality of first material portions and a plurality of second material portions with each of the first material portions being alternately arranged with each of the second material portions, and wherein lattice constants of the first material portions are different from those of the second material portions.

2. The light emitting device according to claim 1, wherein each of the first material portions and each of the second material portions are of lateral dimension from 100 nm to 3000 nm in at least one lateral direction, respectively.

3. The light emitting device according to claim 1, wherein the first and second material portions are made of AlGaN, the Al-composition of the first material portions is higher than the Al-composition of the second material portions, thus the lattice constants of the first material portions are smaller than those of the second material portions.

4. The light emitting device according to claim 3, wherein the n-type layer is made of AlGaN, the Al-composition of the n-type layer is lower than the Al-composition of the first material portions and higher than the Al-composition of the second material portions, thus the lattice constants of the n-type layer are larger than the lattice constants of the first material portions and smaller than the lattice constants of the second material portions.

5. The lattice constant formatted epitaxial template according to claim 1, wherein there is a height difference between the first material portions and the second material portions in a layer growing direction, and the height difference is larger than 100 nanometers.

6. Light emitting device according to claim 1, wherein the n-type layer is an n-type AlGaN layer and the active region emits ultraviolet emissions in the wavelengths of 230-365 nm.

7. A lattice constant formatted epitaxial template comprising:

a starting epitaxial template comprising a base, a plurality of alternately arranged protrusions and depressions on the base;

first material portions epitaxially formed on top of the protrusions and second material portions epitaxially formed in the depressions, wherein lattice constants of the first material portions on the protrusions are different from those of the second material portions in the depressions.

8. The lattice constant formatted epitaxial template according to claim 7, wherein the protrusions are arranged on the base in a one-dimensional or two-dimensional periodic pattern, and the protrusions are of lateral dimension of 100-3000 nm, height of 200-1500 nm and pitch of 200-3500 nm.

9. The lattice constant formatted epitaxial template according to claim 7, wherein the lattice constants of the first material portions are smaller than those of the second material portions.

10. The lattice constant formatted epitaxial template according to claim 7, wherein the starting epitaxial template is made of MN, and the first and second material portions are made of AlGaN, wherein the Al-composition of the first material portions is higher than the Al-composition of the

second material portions, thus the lattice constants of the first material portions are smaller than those of the second material portions.

11. The lattice constant formatted epitaxial template according to claim 7, wherein the starting epitaxial template is made of GaN, and the first and second material portions are made of AlGaN, wherein the Al-composition of the first material portions is higher than the Al-composition of the second material portions, thus the lattice constants of the first material portions are smaller than those of the second material portions.

12. The lattice constant formatted epitaxial template according to claim 7, wherein the starting epitaxial template is made of AlGaN, sapphire, SiC, or Si, and the first and second material portions are made of AlGaN, wherein the Al-composition of the first material portions is higher than the Al-composition of the second material portions, thus the lattice constants of the first material portions are smaller than those of the second material portions.

13. The lattice constant formatted epitaxial template according to claim 7, wherein the first and second material portions are simultaneously formed on the protrusions and in the depressions, respectively, from the same feed material via composition segregation.

14. The lattice constant formatted epitaxial template according to claim 7, wherein there is a height difference between the first material portions and the second material portions in a layer growing direction, and the height difference is larger than 100 nanometers.

15. A light emitting device comprising:

an n-type layer;

a p-type layer;

an active region sandwiched between the n-type layer and the p-type layer;

wherein the n-type layer contains first portions and second portions alternately arranged along a lateral direction of the n-type layer, and lattice constants of the first portions are smaller than lattice constants of the second portions.

16. The light emitting device according to claim 15, wherein each of the first portions and each of the second portions has a lateral dimension from 100 nm to 3000 nm in at least one lateral direction, respectively.

17. The light emitting device according to claim 15, wherein the n-type layer is an unrelaxed layer.

18. The light emitting device according to claim 15, wherein the n-type layer is a fully relaxed layer, and the first and second portions are formed within a sublayer of the fully relaxed n-type layer.

19. The light emitting device according to claim 15, wherein the n-type layer is a AlGaN layer or an InGaN layer.

20. A light emitting device comprising:

a p-type layer;

a light emitting active region; and

the lattice constant formatted epitaxial template according to claim 7;

wherein the active region is directly formed on the first material portions and the second material portions of the lattice constant formatted epitaxial template.

21. The light emitting device according to claim 20, wherein the first and second material portions are made of InGaN and the In-composition of the second material portions is higher than that of the first material portions.

22. The light emitting device according to claim 21, wherein the active region is made of InGaN light emitting quantum wells for emitting visible light.
