(57) **ABSTRACT**

A device and a method for generating input control signals of a serialized compressed scan circuit are provided. A control signal generating device receives a test clock signal from a clock input port and a state enable signal from a state enable bus, and correspondingly generates a shift enable signal, a capture enable signal and a strobe signal. A clock gating device is coupled to the control signal generating device, and receives the shift enable signal, the capture enable signal and the strobe signal. When the shift enable signal is enabled, the clock gating device controls the test clock signal as a serialized scan clock signal. When the strobe signal or the capture enable signal is enabled, the clock gating device controls the test clock signal as a scan clock signal.

DEVICE AND METHOD FOR GENERATING INPUT CONTROL SIGNALS OF A SERIALIZED COMPRESSED SCAN CIRCUIT

CROSS-REFERENCE TO RELATED APPLICATION

This application claims the priority benefit of Taiwan application serial no. 102127222, filed on Jul. 30, 2013. The entirety of the above-mentioned patent application is hereby incorporated by reference herein and made a part of this specification.

TECHNICAL FIELD

The disclosure relates to a device and a method for generating input control signals of a serialized compressed scan circuit.

BACKGROUND

More and more transistors are integrated in a single chip as the complexity of a circuit design growing, it not only increases the execution time of a scan test for a chip but also its test cost. Therefore, a serialized compressed scan architecture (SCSA) with a lot of scan chains but limited test inputs and outputs has been widely used in an integrated circuit (IC) as a design-for-testability (DFT) feature. By increasing the number of scan chains of a circuit, the scan chain length is decreased, which causes the testing time decreased. A test data compressed circuit is further used to reduce test data volume, so as to decrease the test cost. However, since a circuit design complied with a standard test interface has been widely implemented for test integration of an IC, it is difficult to directly implement the test integration of the ICs for the SCSA of a non-standard test interface.

SUMMARY

The present disclosure provides an integrated circuit device, configured to generate input control signals of a serialized compressed scan circuit. The integrated circuit device includes a clock input port, a state enable bus, a control signal generating device and a clock gating device. The clock input port is configured to receive a test clock signal. The state enable bus is configured to receive at least one state enable signal. The control signal generating device is configured to receive the state enable signal of the state enable bus and the test clock signal, and correspondingly generates a shift enable signal, a capture enable signal and a strobe signal. The clock gating device is coupled to the control signal generating device and receives the shift enable signal, the capture enable signal and the strobe signal. When the shift enable signal is enabled, the clock gating device controls the test clock signal as a serialized scan clock signal. When the strobe signal or the capture enable signal is enabled, the clock gating device controls the test clock signal as a scan clock signal. Wherein, the input control signals include the serialized scan clock signal and the scan clock signal.

The present disclosure provides a method for generating input control signals of a serialized compressed scan circuit. The method comprises: generating a shift enable signal, a capture enable signal and a strobe signal according to at least one state enable signal transmitted from a state enable bus and a test clock signal transmitted from a clock input port; controlling the test clock signal as a serialized scan clock signal when the shift enable signal is enabled; and controlling the test clock signal as a scan clock signal when the strobe signal or the capture enable signal is enabled. Wherein, the input control signals include the serialized scan clock signal and the scan clock signal.

Several exemplary embodiments accompanied with figures are described in detail below to further describe the disclosure in details.

BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings are included to provide a further understanding, and are incorporated in and constitute a part of this specification. The drawings illustrate exemplary embodiments and, together with the description, serve to explain the principles of the disclosure.

FIG. **1** illustrates an integrated circuit/chip according to an embodiment of the disclosure.

FIG. **2** is a state diagram of the integrated circuit device of FIG. **1** according to an embodiment of the disclosure.

FIG. **3** illustrates the integrated circuit device of FIG. **1** according to an embodiment of the disclosure.

FIG. **4** illustrates the control signal generating device of FIG. **3** according to an embodiment of the disclosure.

FIG. **5** illustrates the logic operation circuit of FIG. **4** according to an embodiment of the disclosure.

FIG. **6** illustrates the clock gating device of FIG. **3** according to another embodiment of the disclosure.

FIG. **7** is a state timing of the state enable bus State_Enable_Bus of an embodiment of the disclosure.

FIG. **8** is a signal waveform diagram of executing a scan chain test on the serialized compressed scan circuit of FIG. **1** according to an embodiment of the disclosure.

FIG. **9** illustrates the logic operation circuit of FIG. **4** according to another embodiment of the disclosure.

FIG. **10** is a signal waveform diagram of executing a scan chain test on the serialized compressed scan circuit of FIG. **1** according to an embodiment of the disclosure.

FIG. **11** illustrates the control signal generating device of FIG. **3** according to another embodiment of the disclosure.

FIG. **12** illustrates the logic operation circuit of FIG. **11** according to an embodiment of the disclosure.

FIG. **13** is a signal waveform diagram of executing a scan chain test on the serialized compressed scan circuit of FIG. **1** according to an embodiment of the disclosure.

FIG. **14** illustrates the logic operation circuit of FIG. **11** according to another embodiment of the disclosure.

FIG. **15** is a signal waveform diagram of executing a scan chain test on the serialized compressed scan circuit of FIG. **1** according to another embodiment of the disclosure.

FIG. **16** illustrates the logic operation circuit of FIG. **11** according to another embodiment of the disclosure.

FIG. **17** is a signal waveform diagram of executing a scan chain test on the serialized compressed scan circuit of FIG. **1** according to another embodiment of the disclosure.

FIG. **18** illustrates an integrated circuit according to another embodiment of the disclosure.

FIG. **19** illustrates a serialized compressed scan signal generator of FIG. **18** according to an embodiment of the disclosure.

FIG. **20** illustrates a serialized compressed scan signal generator of FIG. **19** according to another embodiment of the disclosure.

FIG. **21** illustrates a serialized compressed scan signal generator of FIG. **19** according to another embodiment of the disclosure.

FIG. **22** illustrates a serialized compressed scan signal generator of FIG. **19** according to another embodiment of the disclosure.

FIG. **23** illustrates a serialized compressed scan signal generator of FIG. **19** according to another embodiment of the disclosure.

FIG. **24** illustrates a serialized compressed scan signal generator of FIG. **19** according to another embodiment of the disclosure.

DETAILED DESCRIPTION OF DISCLOSED EMBODIMENTS

FIG. **1** illustrates an integrated circuit **100** according to an embodiment of the disclosure. The integrated circuit **100** includes a serialized compressed scan circuit **110**, an integrated circuit device **190** and a test access port (TAP) **150**. The integrated circuit **100** may be coupled to a test equipment (not shown) through the TAP **150**, and receives a test data input signal TDI, a test clock signal TCK and a test mode selection signal TMS from the test equipment, and provides a test result data output signal TDO to the test equipment. The test data input signal TDI, the test clock signal TCK and the test mode selection signal TMS could be compliant to IEEE 1149.1 standard. The integrated circuit device **190** generates input control signals of the serialized compressed scan circuit **110**. In the present embodiment, the input control signals of the serialized compressed scan circuit **110** include a shift enable signal SE, a strobe signal Strobe, a serialized scan clock signal SSC and a scan clock signal SC. The integrated circuit device **190** could control all or part of the test clock signal TCK as the serialized scan clock signal SSC. The integrated circuit device **190** could gate all or part of the test clock signal TCK as the scan clock signal SC. Moreover, the test data input signal TDI of the TAP **150** could be coupled to the serialized compressed scan circuit **110** to serve as a serialized scan data input signal SSI, and a serialized scan data output signal SSO of the serialized compressed scan circuit **110** could be serve as the test result data output signal TDO of the TAP **150**.

In the present embodiment of FIG. **1**, the serialized compressed scan circuit **110** includes a deserializer **112**, a decompressor **114**, circuits under test with parallel scan chains **116**, a compressor **115** and a serializer **113**, where the deserializer **112** could be a serial to parallel converter, and the serializer **113** could be a parallel to serial converter. The deserializer **112** converts the serially input (i.e. input in a serial mode) serialized scan data input signal SSI into data D1 having a plurality of bits according to the serialized scan clock signal SSC received from the integrated circuit device **190**. In an embodiment, the serialized scan data input signal SSI could be compressed test data. The decompressor **114** decompresses the data D1 to generate a plurality of batches of data D2. The circuits under test with parallel scan chains **116** includes parallel scan chain (PSC) circuits **117**, where when the scan test is performed, each of the PSC circuit **117** receives the data D2 according to the scan clock signal SC and the shift enable signal SE received from the integrated circuit device **190**, and generates data D3 after the scan test. The operation of the PSC circuit **117** relates to a common digital integrated circuit scan test method. For example, each of the PSC circuits **117** receives one bit of the data D2 in response to the scan clock signal SC, i.e. the scan chain scan and shift one bit. The compressor **115** compresses a plurality batches of the data D3 received from the circuits under test with parallel scan chains **116** to generate data D4 having a plurality of bits. In an embodiment, the data D3 could be a test result, and the data D4 could be a compressed test result. Then, the serializer **113** converts the data D4 into the serialized scan data output signal SSO according to the serialized scan clock signal SSC and the strobe signal Strobe generated by the integrated circuit device **190**. Therefore, the test equipment could determine whether the circuit under test (i.e. the integrated circuit **100**) with parallel scan chains **116** is good or bad according to the test result data output signal TDO which is coupled to the serialized scan data output signal SSO.

FIG. **2** is a state diagram of the integrated circuit device **190** of FIG. **1** according to an embodiment of the disclosure, in which the state of the integrated circuit device **190** is compliant to the IEEE 1149.1 test standard. The integrated circuit device **190** could change its state value thereof according to the test mode selection signal TMS received from the TAP **150**. Generally, a standard TAP state machine is composed of a 4-bit state register where a logic value of the state register represents the current state of the TAP state machine. First, the test mode selection signal TMS determines whether the TAP state machine of the integrated circuit device **190** remains in a test-logic-reset state S**202** (TMS=1) or enters a run-test/idle state S**204** (TMS=0). Under the test-logic-reset state S**202** and the run-test/idle state S**204**, all of test data registers (for example, a bypass register, a boundary scan register, and user-defined data registers) are not activated. Then, when the test mode selection signal TMS is high (TMS=1), the integrated circuit device **190** enters a select-data-register-scan (select-DR-scan) state S**206** from the run-test/idle state S**204**. Otherwise, the integrated circuit device **190** remains in the run-test/idle state S**204**. Thereafter, when the test mode selection signal TMS is low (TMS=0), the integrated circuit device **190** enters a capture-data-register (capture-DR) state S**208** from the select-DR-scan state S**206**.

Then, when the test mode selection signal TMS is low, the integrated circuit device **190** enters a shift-data-register (shift-DR) state S**210** from the capture-DR state S**208**. Otherwise, the integrated circuit device **190** enters an exit1-data-register (exit1-DR) state S**212** from the capture-DR state S**208**.

When the integrated circuit device **190** is in the shift-DR state S**210**, if the test mode selection signal TMS is low, the integrated circuit device **190** remains in the shift-DR state S**210**. Otherwise (TMS=1), integrated circuit device **190** enters the exit1-DR state S**212** from the shift-DR state S**210**.

When the integrated circuit device **190** is in the exit1-DR state S**212**, if the test mode selection signal TMS is low, the integrated circuit device **190** enters a pause-data-register (pause-DR) state S**214** from the exit1-DR state S**212**. Otherwise (TMS=1), the integrated circuit device **190** enters the update-data-register (update-DR) state S**218** from the exit1-DR state S**212**.

When the integrated circuit device **190** is in the pause-DR state S**214**, if the test mode selection signal TMS is low, the integrated circuit device **190** remains in the pause-DR state S**214**. Otherwise (TMS=1), the integrated circuit device **190** enters an exit2-data-register (exit2-DR) state S**216** from the pause-DR state S**214**.

Then, when the test mode selection signal TMS is low, the integrated circuit device **190** returns to the shift-DR state S**210** from the exit2-DR state S**216**. Otherwise (TMS=1), the integrated circuit device **190** enters the update-DR state S**218** from the exit2-DR state S**216**. Then, when the test mode selection signal TMS is low, the integrated circuit device **190** returns to the run-test/idle state S**204** from the update-DR state S**218**. Otherwise (TMS=1), the integrated

circuit device **190** returns to the select-DR-scan state S**206** from the update-DR state S**218**.

Moreover, when the integrated circuit device **190** is in the select-DR-scan state S**206**, and if the test mode selection signal TMS is high (TMS=1), the integrated circuit device **190** enters a select-instruction-register-scan (select-IR-scan) state S**256** from the select-DR-scan state S**206**. Then, when the test mode selection signal TMS is high, the integrated circuit device **190** returns to the test-logic-reset state S**202** from the select-IR-scan state S**256**. Conversely, when the test mode selection signal TMS is low, the integrated circuit device **190** enters a capture-instruction-register (capture-IR) state S**258** from the select-IR-scan state S**256**. Then, when the test mode selection signal TMS is low, the integrated circuit device **190** enters a shift-instruction-register (shift-IR) state S**260** from the capture-IR state S**258**. Otherwise (TMS=1), the integrated circuit device **190** enters an exit1-instruction-register (exit1-IR) state S**262** from the capture-IR state S**258**.

When the integrated circuit device **190** is in the shift-IR state S**260**, if the test mode selection signal TMS is low, the integrated circuit device **190** remains in the shift-IR state S**260**. Otherwise (TMS=1), the integrated circuit device **190** enters the exit1-IR state S**262** from the shift-IR state S**260**. When the integrated circuit device **190** is in the exit1-IR state S**262**, if the test mode selection signal TMS is low, the integrated circuit device **190** enters a pause-instruction-register (pause-IR) state S**264** from the exit1-IR state S**262**. Otherwise (TMS=1), the integrated circuit device **190** enters an update-instruction-register (update-IR) state S**268** from the exit1-IR state S**262**. When the integrated circuit device **190** is in the pause-IR state S**264**, if the test mode selection signal TMS is low, the integrated circuit device **190** remains in the pause-IR state S**264**. Otherwise (TMS=1), the integrated circuit device **190** enters an exit2-instruction-register (exit2-IR) state S**266** from the pause-IR state S**264**. Then, when the test mode selection signal TMS is low, the integrated circuit device **190** returns to the shift-IR state S**260** from the exit2-IR state S**266**. Otherwise (TMS=1), the integrated circuit device **190** enters the update-IR state S**268** from the exit2-IR state S**266**. Thereafter, when the test mode selection signal TMS is low, the integrated circuit device **190** returns to the run-test/idle state S**204** from the update-IR state S**268**. Otherwise (TMS=1), the integrated circuit device **190** returns to the select-DR-scan state S**206** from the update-IR state S**268**.

FIG. **3** illustrates the integrated circuit device **190** of FIG. **1** according to an embodiment of the disclosure. The integrated circuit device **190** includes a state enable bus State_Enable_Bus, a control signal generating device **310** and a clock gating device **320**. The state enable bus State_Enable_Bus receives/transmits at least one state enable signal. The control signal generating device **310** is coupled to the state enable bus State_Enable_Bus for receiving the state enable signal. The control signal generating device **310** receives the test clock signal TCK, and correspondingly generates a shift enable signal Shift_en, a capture enable signal Capture_en and a strobe signal Strobe according to the state enable signals on the state enable bus State_Enable_Bus. In the present embodiment of FIG. **3**, the shift enable signal Shift_en is outputted to the serialized compressed scan circuit **110** to serve as the shift enable signal SE.

The clock gating device **320** is coupled to the control signal generating device **310** for receiving the shift enable signal Shift_en, the capture enable signal Capture_en and the strobe signal Strobe. The clock gating device **320** receives and controls the test clock signal TCK as the serialized scan clock signal SSC when the shift enable signal Shift_en is enabled. The clock gating device **320** controls the test clock signal TCK as the scan clock signal SC when the strobe signal Strobe or the capture enable signal Capture_en is enabled.

FIG. **4** illustrates the control signal generating device **310** of FIG. **3** according to an embodiment of the disclosure. The control signal generating device **310** includes a logic operation circuit **450**, a first negative edge-triggered register **413**, a second negative edge-triggered register **414** and a third negative edge-triggered register **415**. The logic operation circuit **450** is coupled to the state enable bus State_Enable_Bus for receiving the state enable signal. For example, the logic operation circuit **450** may receive an exit1-data-register (exit1-DR) state enable signal, an exit2-data-register (exit2-DR) state enable signal, a shift-data-register (shift-DR) state enable signal, a pause-data-register (pause-DR) state enable signal and/or a capture-data-register (capture-DR) state enable signal from the state enable bus State_Enable_Bus. According to the state enable signals of the state enable bus State_Enable_Bus, the logic operation circuit **450** correspondingly generating a first logic signal LS1, a second logic signal LS2 and a third logic signal LS3.

In the present embodiment of FIG. **4**, the registers **413**, **414** and **415** may be flip-flops (FFs). The input terminal of the first negative edge-triggered register **413** is coupled to the logic operation circuit **450** for receiving the first logic signal LS1. The negative edge-triggered terminal of the first negative edge-triggered register **413** is coupled to the test clock signal TCK. The output terminal of the first negative edge-triggered register **413** is coupled to the clock gating device **320** for providing the shift enable signal Shift_en. The input terminal of the second negative edge-triggered register **414** is coupled to the logic operation circuit **450** for receiving the second logic signal LS2. The negative edge-triggered terminal of the second negative edge-triggered register **414** is coupled to the test clock signal TCK. The output terminal of the second negative edge-triggered register **414** is coupled to the clock gating device **320** for providing the strobe signal Strobe. The input terminal of the third negative edge-triggered register **415** is coupled to the logic operation circuit **450** for receiving the third logic signal LS3. The negative edge-triggered terminal of the third negative edge-triggered register **415** is coupled to the test clock signal TCK. The output terminal of the third negative edge-triggered register **415** is coupled to the clock gating device **320** for providing the capture enable signal Capture_en.

In some embodiments, the logic operation circuit **450** may enable the first logic signal LS1 when the exit1-DR state enable signal Exit1-DR, the exit2-DR state enable signal Exit2-DR, the shift-DR state enable signal Shift-DR or the pause-DR state enable signal Pause-DR is enabled. The logic operation circuit **450** may enable the second logic signal LS2 when the exit1-DR state enable signal Exit1-DR or the exit2-DR state enable signal Exit2-DR is enabled. The logic operation circuit **450** may enable the third logic signal LS3 when the capture-DR state enable signal Capture-DR is enabled.

FIG. **5** illustrates the logic operation circuit **450** of FIG. **4** according to an embodiment of the disclosure. The logic operation circuit **450** includes an OR gate **510**, an OR gate **520** and a wire **530**. The first input terminal of the OR gate **510** is coupled to the state enable bus State_Enable_Bus for receiving the shift-DR state enable signal Shift-DR. The second input terminal of the OR gate **510** is coupled to the

state enable bus State_Enable_Bus for receiving the pause-DR state enable signal Pause-DR. The output terminal of the OR gate **510** generates the first logic signal LS **1** to the input terminal of the first negative edge-triggered register **413**. The first input terminal of the OR gate **520** is coupled to the state enable bus State_Enable_Bus for receiving the exit1-DR state enable signal Exit1-DR. The second input terminal of the OR gate **520** is coupled to the state enable bus State_Enable_Bus for receiving the exit2-DR state enable signal Exit2-DR. The output terminal of the OR gate **520** is coupled to the third input terminal of the OR gate **510** and the input terminal of the second negative edge-triggered register **414** for generating/providing the second logic signal LS2. The first terminal of the wire **530** is coupled to the state enable bus State_Enable_Bus for receiving the capture-DR state enable signal Capture-DR. The second terminal of the wire **530** outputs the capture-DR state enable signal Capture-DR to serve as the third logic signal LS3.

FIG. **6** illustrates the clock gating device **320** of FIG. **3** according to an embodiment of the disclosure. The clock gating device **320** includes an OR gate **421**, a AND gate **422** and a AND gate **423**. The first input terminal of the OR gate **421** is coupled to the control signal generating device **310** for receiving the signal Strobe. The second input terminal of the OR gate **421** is coupled to the control signal generating device **310** for receiving the signal Capture_en. The first input terminal of the AND gate **422** is coupled to the output terminal of the OR gate **421**. The second input terminal of the AND gate **422** is coupled to the test clock signal TCK. The output terminal of the AND gate **422** generates the scan clock signal SC to the serialized compressed scan circuit **110**. The first input terminal of the AND gate **423** is coupled to the control signal generating device **310** for receiving the shift enable signal shift_en. The second input terminal of the AND gate **423** is coupled to the test clock signal TCK. The output terminal of the AND gate **423** generates the serialized scan clock signal SSC to the serialized compressed scan circuit **110**.

FIG. **7** is a state timing of the state enable bus State_Enable_Bus of an embodiment of the disclosure. Referring to FIG. **1**, FIG. **2**, and FIG. **7**, when the integrated circuit device **190** enters the capture-DR state S**208**, the capture-DR state enable signal Capture-DR is transited from low to high, and the other state enable signals of the state enable bus State_Enable_Bus are still remained low. Then, when the integrated circuit device **190** enters the shift-DR state S**210** from the capture-DR state S**208**, the capture-DR state enable signal Capture-DR is transited from high to low, and the shift-DR state enable signal Shift-DR is transited from low to high, and the others are deduced by analogy. In another embodiment, a polarity of the state enable bus State_Enable_Bus is reversed, namely, when the integrated circuit device **190** enters the capture-DR state S**208**, the capture-DR state enable signal Capture-DR is transited from high to low, and the other state enable signals are remained at high, and the others are deduced by analogy.

FIG. **8** is a signal waveform diagram of executing a scan chain test on the serialized compressed scan circuit **110** of FIG. **1** according to an embodiment of the disclosure. In FIG. **8**, state transition of the integrated circuit device **190** compliant to the IEEE 1149.1 test standard (for example, the TAP state transitions as FIG. **2**). Referring to FIG. **2**, FIG. **3**, FIG. **4**, FIG. **5**, FIG. **6** and FIG. **8**, in the present embodiment, the state of the integrated circuit device **190** is sequentially transited from the test-logic-reset state S**202**, the run-test/idle state S**204**, and the select-DR-scan state S**206** into the select-IR-scan state S**256**. After the instruction is loaded into the instruction register of the integrated circuit device **190**, the state of the integrated circuit device **190** is returned to the select-DR-scan state S**206** and then transited into the capture-DR state S**208**.

When the state of the integrated circuit device **190** is the capture-DR state S**208**, the TAP state machine of the integrated circuit device **190** enables the capture-DR state enable signal Capture-DR of the state enable bus State_Enable_Bus. The control signal generating device **310** and the clock gating device **320** generates the scan clock signal SC according to the capture-DR state enable signal Capture-DR and the test clock signal TCK. Then, the state of the integrated circuit device **190** enters the shift-DR state S**210** from the capture-DR state S**208**. When the state of the integrated circuit device **190** is the shift-DR state S**210**, the TAP state machine of the integrated circuit device **190** enables the shift-DR state enable signal Shift-DR of the state enable bus State_Enable_Bus, such that the shift enable signal SE is transited from low to high. Moreover, the decompressor **114** outputs the test data D2 to the PSC circuits **117**, where the compressed test data (SSI) is serially input to the deserializer **112**, and the serializer **113** serially outputs the compressed test result (SSO). Then, the TAP state machine of the integrated circuit device **190** remains in the shift-DR state S**210** until TMS transits to high, and then the TAP state machine of the integrated circuit device **190** transits to the exit1-DR state S**212**.

When the state of the integrated circuit device **190** is the exit1-DR state S**212**, the TAP state machine of the integrated circuit device **190** enables the exit1-DR state enable signal Exit1-DR of the state enable bus State_Enable_Bus, such that the OR gate **520** output high. The second negative edge-triggered register **414** transits the signal Strobe to high according to output of the OR gate **520** and the test clock signal TCK. Therefore, the decompressor **114** outputs the test data D2 to the PSC circuits **117**, and the next compressed test data (SSI) is serially input to the deserializer **112**, where the serializer **113** serially outputs the compressed test result (SSO). Then, the state of the integrated circuit device **190** transits to the pause-DR state S**214** or the update-DR state S**218** from the exit1-DR state S**212**. When the state of the integrated circuit device **190** is the pause-DR state S**214**, the TAP state machine of the integrated circuit device **190** enables the pause-DR state enable signal Pause-DR of the state enable bus State_Enable_Bus, such that the shift enable signal SE remains in the high logic level. Then, the state of the integrated circuit device **190** remains in the pause-DR state S**214** until TMS transits to high, and then the state of the integrated circuit device **190** enters the exit2-DR state S**216**.

When the state of the integrated circuit device **190** is the exit2-DR state S**216**, the TAP state machine of the integrated circuit device **190** enables the exit2-DR state enable signal Exit2-DR of the state enable bus State_Enable_Bus, such that the OR gate **520** output high. The second negative edge-triggered register **414** transits the signal Strobe from low to high according to output of the OR gate **520** and the test clock signal TCK. the AND gate **422** controls the test clock signal TCK as the scan clock signal SC to the PSC circuits **117** of FIG. **1** when the signal Strobe is enabled. Therefore, the decompressor **114** outputs the test data D2 to the PSC circuits **117**, and the next compressed test data (SSI) is serially input to the deserializer **112**, where the serializer **113** serially outputs the compressed test result (SSO). Then, the state value TSM is transited to the shift-DR state S**210** or the update-DR state S**218** from the exit2-DR state S**216**.

When the state of the integrated circuit device **190** is the shift-DR state S**210**, the TAP state machine of the integrated circuit device **190** enables the shift-DR state enable signal Shift-DR of the state enable bus State_Enable_Bus, such that the shift enable signal SE remains high. Then, the integrated circuit device **190** remains in the shift-DR state S**210** until the integrated circuit device **190** enters the exit1-DR state S**212**. When the state of the integrated circuit device **190** is the exit1-DR state S**212**, the TAP state machine of the integrated circuit device **190** enables the exit1-DR state enable signal Exit1-DR coupled to the OR gate **520** for enabling the scan clock signal SC and the strobe signal Strobe. Then, the state of the integrated circuit device **190** is transited from the exit1-DR state S**212** or the exit2-DR state S**216** to the update-DR state S**218**. Then, the state of the integrated circuit device **190** is transited from the update-DR state S**218** to the select-DR-scan state S**206**. Finally, the state of the integrated circuit device **190** is transited from the select-DR-scan state S**206** to the capture-DR state S**208**, such that the test result is captured to the PSC circuits **117** of the serialized compressed scan circuit **110** of FIG. **1**.

Similarly, when the state of the integrated circuit device **190** is transited from the exit1-DR state S**212** (or the exit2-DR state S**216**) to the update-DR state S**218**, the TAP state machine of the integrated circuit device **190** does not enable any one of the shift-DR state enable signal Shift-DR, the pause-DR state enable signal Pause-DR, the exit1-DR state enable signal Exit1-DR and the exit2-DR state enable signal Exit2-DR. Therefore, the shift enable signal SE is transited from high to low. In detail, the test equipment (not shown) could transmit an instruction during a time period P1 through the TAP (for example, the TAP **150** of FIG. **1**) of the integrated circuit. Then, the integrated circuit device **190** performs a scan shift operation during a time period P2 to transmit the test data to the PSC circuits **117** of the serialized compressed scan circuit **110** of FIG. **1**, and meanwhile outputs the test result data stored in the serialized compressed scan circuit **110** of FIG. **1**. Then, during a time period P3, the test result of the circuit under test is captured and stored in the PSC circuits **117** of the serialized compressed scan circuit **110** of FIG. **1**. Moreover, during the time period P2, the state of the integrated circuit device **190** could be returned to the shift-DR state S**210** from the exit2-DR state S**216** to continue the scan shift operation until transmission of the test data to the PSC circuits **117** of the serialized compressed scan circuit **110** of FIG. **1** is completed. Now, the state of the integrated circuit device **190** is transited from the exit1-DR state S**212** (or the exit2-DR state S**216**) to the update-DR state S**218**, and is returned to the capture-DR state S**208** from the select-DR-scan state S**206**, so as to output the test result during a time period P3.

FIG. **9** illustrates the logic operation circuit **450** of FIG. **4** according to another embodiment of the disclosure. The logic operation circuit **450** of FIG. **9** includes a NOR gate **910**, a flip-flop (FF) **920**, an NOR gate **930** and an OR gate **940**. The inverting input terminal of the NOR gate **910** is coupled to the state enable bus State_Enable_Bus for receiving the pause-DR state enable signal Pause-DR. The non-inverting input terminal of the NOR gate **910** is configured to receive the test mode selection signal TMS from the TAP **150**. The input terminal of the flip-flop **920** is coupled to the output terminal of the NOR gate **910**. The positive edge-triggered terminal of the flip-flop **920** is coupled to the test clock signal TCK. The output terminal of the flip-flop **920** provides the third logic signal LS3 to the third negative edge-triggered register **415**. The inverting input terminal of the NOR gate **930** is coupled to the state enable bus State_Enable_Bus for receiving the pause-DR state enable signal Pause-DR. The non-inverting input terminal of the NOR gate **930** is coupled to the output terminal of the flip-flop **920**. The output terminal of the NOR gate **930** provides the second logic signal LS2 to the second negative edge-triggered register **414**. The first input terminal of the OR gate **940** is coupled to the output terminal of the NOR gate **930**. The second input terminal of the OR gate **940** is coupled to the state enable bus State_Enable_Bus for receiving the shift-DR state enable signal Shift-DR. The third input terminal of the OR gate **940** is coupled to the state enable bus State_Enable_Bus for receiving the exit1-DR state enable signal Exit1-DR. The fourth input terminal of the OR gate **940** is coupled to the state enable bus State_Enable_Bus for receiving the exit2-DR state enable signal Exit2-DR. The output terminal of the OR gate **940** provides the first logic signal LS1 to the first negative edge-triggered register **413**.

FIG. **10** is a signal waveform diagram of executing a scan chain test on the serialized compressed scan circuit **110** of FIG. **1** according to an embodiment of the disclosure. In FIG. **10**, state transition of the integrated circuit device **190** compliant to the IEEE 1149.1 test standard (for example, the TAP state transitions as FIG. **2**). Referring to FIG. **2**, FIG. **3**, FIG. **4**, FIG. **6**, FIG. **9** and FIG. **10**, in the present embodiment, the state of the integrated circuit device **190** is sequentially transited from the test-logic-reset state S**202**, the run-test/idle state S**204**, and the select-DR-scan state S**206** to the select-IR-scan state S**256**. After the instruction is loaded to the instruction register of the integrated circuit device **190**, the state of integrated circuit device **190** returns to the select-DR-scan state S**206** and then transits to the shift-DR state S**210** through the capture-DR state S**208**. When the state of the integrated circuit device **190** is the shift-DR state S**210**, the TAP state machine of the integrated circuit device **190** enables the shift-DR state enable signal Shift-DR on the state enable bus State_Enable_Bus, and the shift enable signal SE is transited from low to high. Then, the integrated circuit device **190** remains in the shift-DR state S**210** until the test mode select signal TMS is high and then enters the exit1-DR state S**212**. When the state of the integrated circuit device **190** is the exit1-DR state S**212**, the TAP state machine of the integrated circuit device **190** enables the exit1-DR state enable signal Exit1-DR on the state enable bus State_Enable_Bus, such that the shift enable signal SE remains in high. Then, the state of the integrated circuit device **190** is transited from the exit1-DR state S**212** to the pause-DR state S**214**.

When the state of the integrated circuit device **190** is the pause-DR state S**214**, the TAP state machine of the integrated circuit device **190** enables the pause-DR state enable signal Pause-DR on the state enable bus State_Enable_Bus and the strobe signal Strobe, while the shift enable signal SE remains in high. Then, when the test mode selection signal TMS is high, and the TAP state machine is transited from the pause-DR state S**214** to the exit2-DR state S**216**, the TAP state machine enables the exit2-DR state enable signal Exit2-DR on the state enable bus State_Enable_Bus, while the shift enable signal SE remains in high. Then, the state of the integrated circuit device **190** is returned to the shift-DR state S**210** from the exit2-DR state S**216**. Then, when the TAP state machine of the integrated circuit device **190** is sequentially transited from the shift-DR state S**210**, the exit1-DR state S**212** to the pause-DR state S**214**, and the test mode selection signal TMS is low, the integrated circuit device **190** remains in the pause-DR state S**214**, and the shift

enable signal SE is transited from high to low. Therefore, the test result from a test pattern has been captured. Then, when the test mode selection signal TMS is high, and the TAP state machine of the integrated circuit device **190** is transited from the pause-DR state S**214** to the exit2-DR state S**216**, the TAP state machine enables the exit2-DR state enable signal Exit2-DR on the state enable bus State_Enable_Bus, such that the shift enable signal SE is transited to high, so as to perform the scan shift operation on the other test pattern.

In detail, by coupling to the TAP (for example, the TAP **150** of FIG. **1**) of the integrated circuit, the test equipment could transmit the instruction during the time period P1 in FIG. **10**. Then, the integrated circuit device **190** performs the scan shift operation during the time period P2 in FIG. **10**. Then, during the time period P3 in FIG. **10**, the test result of the circuit under test is captured and stored in the PSC circuits **117** of the serialized compressed scan circuit **110** of FIG. **1**. Then, the integrated circuit device **190** performs the scan shift operation on the second test pattern during the time period P4 in FIG. **10**. Then, during the time period P5 in FIG. **10**, the test result of the circuit under test is captured and stored in the PSC circuits **117** of the serialized compressed scan circuit **110** of FIG. **1**.

FIG. **11** illustrates the control signal generating device **310** of FIG. **3** according to another embodiment of the disclosure. The control signal generating device **310** includes a logic operation circuit **650**, a first negative edge-triggered register **611**, a second negative edge-triggered register **612** and a negative edge-triggered counter **613**. The logic operation circuit **650** is coupled to the state enable bus State_Enable_Bus for receiving the at least one state enable signal, and correspondingly generates a first logic signal LS4 and a second logic signal LS5. For example, the logic operation circuit **650** may receive an exit1-data-register (exit1-DR) state enable signal Exit1-DR, an exit2-data-register (exit2-DR) state enable signal Exit2-DR, a shift-data-register (shift-DR) state enable signal Shift-DR, a pause-data-register (pause-DR) state enable signal Pause-DR and/or a capture-data-register (capture-DR) state enable signal Capture-DR from the state enable bus State_Enable_Bus.

In the present embodiment of FIG. **11**, the registers **611** and **612** may be flip-flops (FFs). The input terminal of the first negative edge-triggered register **611** is coupled to the logic operation circuit **650** for receiving the first logic signal LS4. The negative edge-triggered terminal of the first negative edge-triggered register **611** is coupled to the test clock signal TCK. The output terminal of the first negative edge-triggered register **611** is coupled to the clock gating device **320** for providing the shift enable signal Shift_en. The input terminal of the second negative edge-triggered register **612** is coupled to the logic operation circuit **650** for receiving the second logic signal LS5. The negative edge-triggered terminal of the second negative edge-triggered register **612** is coupled to the test clock signal TCK. The output terminal of the second negative edge-triggered register **612** is coupled to the clock gating device **320** for providing the capture enable signal Capture_en. The input terminal of the negative edge-triggered counter **613** is coupled to the output terminal of the first negative edge-triggered register **611** for receiving the shift enable signal Shift_en. The negative edge-triggered terminal of the negative edge-triggered counter **613** is coupled to the test clock signal TCK. The output terminal of the negative edge-triggered counter **613** is coupled to the clock gating device **320** for providing the strobe signal Strobe. Wherein, cyclic counting of the negative edge-triggered counter **613** from a first value to a second value is activated when the shift enable signal Shift_en is enabled and the test clock signal TCK is at negative edge. In some embodiments, a difference between the second value and the first value may be a serializer bit length (e.g. bit length of the serializer **113** of FIG. **1**) minus one or a deserializer bit length (e.g. bit length of the deserializer **112** of FIG. **1**) minus one.

FIG. **12** illustrates the logic operation circuit **650** of FIG. **11** according to an embodiment of the disclosure. The logic operation circuit **650** includes a first wire **651** and a second wire **652**. The first terminal of the first wire **651** is coupled to the state enable bus State_Enable_Bus for receiving the shift-DR state enable signal Shift-DR. The second terminal of the first wire **651** output the shift-DR state enable signal Shift-DR to serve as the first logic signal LS4. The first terminal of the second wire **652** is coupled to the state enable bus State_Enable_Bus for receiving the capture-DR state enable signal Capture-DR. The second terminal of the second wire **652** output the capture-DR state enable signal Capture-DR to serve as the second logic signal LS5.

FIG. **13** is a signal waveform diagram of executing a scan chain test on the serialized compressed scan circuit **110** of FIG. **1** according to an embodiment of the disclosure. In FIG. **13**, state transition of the integrated circuit device **190** compliant to the IEEE 1149.1 test standard (for example, the TAP state transitions as FIG. **2**). Referring to FIG. **2**, FIG. **3**, FIG. **6**, FIG. **11**, FIG. **12** and FIG. **13**, in the present embodiment, the state of the integrated circuit device **190** sequentially transits from the test-logic-reset state S**202**, the run-test/idle state S**204**, and the select-DR-scan state S**206** to enter the select-IR-scan state S**256**, and after the instruction is loaded to the instruction register of the integrated circuit device **190**, the state of the integrated circuit device **190** is returned to the select-DR-scan state S**206** and then entered the capture-DR state S**208**. When the state of the integrated circuit device **190** is the capture-DR state S**208**, the TAP state machine of the integrated circuit device **190** enables the capture-DR state enable signal Capture-DR coupled to the second negative edge-triggered register **612** through the state enable bus State_Enable_Bus for enabling the scan clock signal SC. Then, the state of the integrated circuit device **190** transits to the shift-DR state S**210** from the capture-DR state S**208**.

When the state of the integrated circuit device **190** is the shift-DR state S**210**, the TAP state machine of the integrated circuit device **190** enables the shift-DR state enable signal Shift-DR on the state enable bus State_Enable_Bus, such that the shift enable signal SE is transited from low to high. Moreover, the decompressor **114** outputs the test data D2 to the PSC circuits **117**, where the compressed test data (SSI) is serially input to the deserializer **112**, and the serializer **113** serially outputs the compressed test result (SSO) while the shift enable signal SE is enabled. When the enable signal Shift_en is high, the counter **613** counts the number of the negative edges (falling edges) of the test clock signal TCK that the integrated circuit device **190** remains in the shift-DR state S**210**. Then, when the counting result of the counter **613** reaches a specific value, the counter **613** enables the strobe signal Strobe, where the specific value is determined by a conversion bit length of the deserializer **112** or the serializer **113** of FIG. **1**. Then, the clock gating device **320** generates the scan clock signal SC in response to the strobe signal Strobe. According to the aforementioned descriptions, after processing of a test pattern receiving from the test equipment is completed, the state of the integrated circuit device **190** is sequentially transited from the shift-DR state S**210**, the exit1-DR state S**212**, the update-DR state S**218**,

the select-DR-scan state **S206** to the capture-DR state **S208**. Moreover, when the state of the integrated circuit device **190** is transited from the shift-DR state **S210** to the exit1-DR state **S212**, the TAP state machine of the integrated circuit device **190** disables the shift-DR state enable signal Shift-DR, and the shift enable signal SE is transited from high to low.

In detail, the test equipment could transmit an instruction during the time period P1 in FIG. **13** through the TAP (for example, the TAP **150** of FIG. **1**) of the integrated circuit. Then, the integrated circuit device **190** performs a scan shift operation during the time period P2 in FIG. **13** to transmit the test data to the PSC circuits **117** of the serialized compressed scan circuit **110** of FIG. **1**, and meanwhile outputs the test result data stored in the serialized compressed scan circuit **110** of FIG. **1**. Then, during the time period P3 in FIG. **13**, the test result of the circuit under test is captured and stored in the PSC circuits **117** of the serialized compressed scan circuit **110** of FIG. **1**. Moreover, during the time period P2 in FIG. **13**, the state of the integrated circuit device **190** is remained in the shift-DR state **S210** to continue the scan shift operation until transmission of the test data to the PSC circuits **117** of the serialized compressed scan circuit **110** of FIG. **1** is completed. Now, the state of the integrated circuit device **190** is transited from the shift-DR state **S210** to the exit1-DR state **S212**. Then, the state of the integrated circuit device **190** is transited from the exit1-DR state **S212** to the update-DR state **S218**, and returns to the capture-DR state **S208** from the select-DR-scan state **S206**, so as to output the test result, where the test result is captured to the PSC circuits **117**.

FIG. **14** illustrates the logic operation circuit **650** of FIG. **11** according to another embodiment of the disclosure. The logic operation circuit **650** includes a first wire **653** and a second wire **654**. The first terminal of the first wire **653** is coupled to the state enable bus State_Enable_Bus for receiving a pause-DR state enable signal Pause-DR. The second terminal of the first wire **653** output the pause-DR state enable signal Pause-DR to serve as the first logic signal LS4. The first terminal of the second wire **654** is coupled to the state enable bus State_Enable_Bus for receiving a capture-DR state enable signal Capture-DR. The second terminal of the second wire **654** output the capture-DR state enable signal Capture-DR to serve as the second logic signal LS5.

FIG. **15** is a signal waveform diagram of executing a scan chain test on the serialized compressed scan circuit **110** of FIG. **1** according to another embodiment of the disclosure. In FIG. **15**, state transition of the integrated circuit device **190** compliant to the IEEE 1149.1 test standard (for example, the TAP state transitions as FIG. **2**). Referring to FIG. **2**, FIG. **3**, FIG. **6**, FIG. **11**, FIG. **14** and FIG. **15**, in the present embodiment, the state of the integrated circuit device **190** sequentially transits from the test-logic-reset state **S202**, the run-test/idle state **S204**, and the select-DR-scan state **S206** to enter the select-IR-scan state **S256**, and after the instruction is loaded to the instruction register of the integrated circuit device **190**, the state of the integrated circuit device **190** is returned to the select-DR-scan state **S206** and then entered the capture-DR state **S208**. When the state of the integrated circuit device **190** is the capture-DR state **S208**, the TAP state machine of the integrated circuit device **190** enables the capture-DR state enable signal Capture-DR coupled to the second negative edge-triggered register **612** through the state enable bus State_Enable_Bus for enabling the scan clock signal SC. Then, the state of the integrated circuit device **190** transits from the capture-DR state **S208** to the exit1-DR state **S212** and then to the pause-DR state **S214**.

When the state of the integrated circuit device **190** is the pause-DR state **S214**, the TAP state machine of the integrated circuit device **190** enables the pause-DR state enable signal Pause-DR on the state enable bus State_Enable_Bus for transiting the shift enable signal SE from low to high. Therefore, the decompressor **114** outputs the test data D2 to the PSC circuits **117**, where the compressed test data SSI is serially input to the deserializer **112**, and the serializer **113** serially outputs the compressed test result (SSO). When the enable signal Shift_en is high, the counter **613** counts the number of negative edges of the test clock signal TCK that the integrated circuit device **190** remains in the pause-DR state **S214**. Then, when the counting result of the counter **613** reaches a specific value, the counter **613** enables the strobe signal Strobe, where the specific value is determined by a conversion bit length of the deserializer **112** or the serializer **113** of FIG. **1**. Then, the clock gating device **320** generates the scan clock signal SC in response to the strobe signal Strobe. According to the aforementioned descriptions, after processing of a test pattern is completed, the state of the integrated circuit device **190** sequentially transits from the pause-DR state **S214**, the exit2-DR state **S216**, the update-DR state **S218**, the select-DR-scan state **S206** to the capture-DR state **S208**. Therefore, the test result is captured to the PSC circuits **117**. Moreover, when the state of the integrated circuit device **190** is transited from the pause-DR state **S214** to the exit2-DR state **S216**, the TAP state machine of the integrated circuit device **190** disables the pause-DR state enable signal Pause-DR, and the shift enable signal SE is transited from high to low.

FIG. **16** illustrates the logic operation circuit **650** of FIG. **11** according to another embodiment of the disclosure. The logic operation circuit **650** includes a first OR gate **655** and a second OR gate **656**. The first input terminal of the first OR gate **655** is coupled to the state enable bus State_Enable_Bus for receiving the shift-DR state enable signal Shift-DR. The second input terminal of the first OR gate **655** is coupled to the state enable bus State_Enable_Bus for receiving the pause-DR state enable signal Pause-DR. The output terminal of the first OR gate **655** generates the first logic signal LS4 to the input terminal of the first negative edge-triggered register **611**. The first input terminal of the second OR gate **656** is coupled to the state enable bus State_Enable_Bus for receiving the exit1-DR state enable signal Exit1-DR. The second input terminal of the second OR gate **656** is coupled to the state enable bus State_Enable_Bus for receiving an exit2-DR state enable signal Exit2-DR. The output terminal of the second OR gate **656** generates the second logic signal LS5 to the input terminal of the second negative edge-triggered register **612**.

FIG. **17** is a signal waveform diagram of executing a scan chain test on the serialized compressed scan circuit **110** of FIG. **1** according to another embodiment of the disclosure. In FIG. **17**, state transition of the integrated circuit device **190** compliant to the IEEE 1149.1 test standard (for example, the TAP state transitions as FIG. **2**). Referring to FIG. **2**, FIG. **3**, FIG. **6**, FIG. **11**, FIG. **16** and FIG. **17**, in the present embodiment, the state of the integrated circuit device **190** sequentially transits from the test-logic-reset state **S202**, the run-test/idle state **S204**, and the select-DR-scan state **S206** to the select-IR-scan state **S256**, and after the instruction is loaded to the instruction register of the integrated circuit device **190**, the state of the integrated circuit device

190 sequentially enters to the select-DR-scan state S206, the capture-DR state S208 and the shift-DR state S210.

When the state of the integrated circuit device 190 is the shift-DR state S210, the TAP state machine of the integrated circuit device 190 enables the shift-DR state enable signal Shift-DR on the state enable bus State_Enable_Bus, and the shift enable signal SE is transited from low to high. Moreover, the decompressor 114 outputs the test data D2 to the PSC circuits 117, where the compressed test data SS1 is serially input to the deserializer 112, and the serializer 113 serially outputs the compressed test result (SSO). When the enable signal Shift_en is high, the counter 613 counts the number of negative edges of the test clock signal TCK that the integrated circuit device 190 remains in the shift-DR state S210. Then, when the counting result of the counter 613 reaches a specific value, the counter 613 enables the strobe signal Strobe, where the specific value is determined by a conversion bit length of the deserializer 112 or the serializer 113 of FIG. 1. Then, the clock gating device 320 generates the scan clock signal SC in response to the strobe signal Strobe. After processing of a test pattern is completed, the state of the integrated circuit device 190 is sequentially transited from the shift-DR state S210 and the exit1-DR state S212 to the pause-DR state S214. Moreover, when the state of the integrated circuit device 190 is transited from the shift-DR state S210 to the exit1-DR state S212, the TAP state machine of the integrated circuit device 190 disables the shift-DR state enable signal Shift-DR, and the shift enable signal SE is transited from high to low.

In detail, the test equipment could transmit the serialized compressed scan instruction during the time period P1 in FIG. 17 through the TAP (for example, the TAP 150 of FIG. 1) of the integrated circuit. Then, the integrated circuit device 190 performs a scan shift operation during the time period P2 in FIG. 17 to transmit the test data to the PSC circuits 117 of the serialized compressed scan circuit 110 of FIG. 1, and meanwhile outputs the test result data stored in the serialized compressed scan circuit 110 of FIG. 1. Then, during the time period P3 in FIG. 17, the test result of the circuit under test is captured and stored in the PSC circuits 117 of the serialized compressed scan circuit 110 of FIG. 1. Then, the state of the integrated circuit device 190 is transited from the exit1-DR state S212 to the pause-DR state S214. When the state of the integrated circuit device 190 is the pause-DR state S214, the TAP state machine of the integrated circuit device 190 enables the pause-DR state enable signal Pause-DR on the state enable bus State_Enable_Bus, and the shift enable signal SE is transited from low to high. Therefore, the counter 613 counts the number of negative edges of the test clock signal TCK that the integrated circuit device 190 in the pause-DR state S214. Moreover, the decompressor 114 outputs the test data to the PSC circuits 117, where the compressed test data is serially input to the deserializer 112, and the serializer 113 serially outputs the compressed test result. Then, when the counting result of the counter 613 reaches a specific value, the counter 613 enables the strobe signal Strobe. Then, the clock gating device 320 generates the scan clock signal SC in response to the strobe signal Strobe. Therefore, after processing of a second test pattern is completed, the state of the integrated circuit device 190 is sequentially transited from the pause-DR state S214, the exit2-DR state S216, the update-DR state S218, the select-DR-scan state S206 to the capture-DR state S208. Moreover, when the state of the integrated circuit device 190 is transited from the pause-DR state S214 to the exit2-DR state S216, the TAP state machine of the integrated circuit device 190 disables the state indication signal pause-DR, and the shift enable signal SE is transited from high to low. In detail, the integrated circuit device 190 performs the scan shift operation on the second test pattern during a time period P4 in FIG. 17. Then, during a time period P5 in FIG. 17, the test equipment captures the test result through the TAP.

FIG. 18 illustrates an integrated circuit 1800 according to another embodiment of the disclosure. The integrated circuit 1800 includes a serialized compressed scan circuit 110, an integrated circuit device 190, a multiplexer 140 and a test access port (TAP) 150. The integrated circuit 1800 may be coupled to a test equipment (not shown) through the TAP 150, and receives a test data input signal TDI, a test clock signal TCK, a test mode selection signal TMS and an optional test reset signal TRST from the test equipment, and provides a test result data output signal TDO to the test equipment. The integrated circuit 1800 may be implemented with reference to FIG. 1. The test data input signal TDI, a test clock signal TCK and the test mode selection signal TMS could be compliant to IEEE 1149.1 standard. The integrated circuit device 190 generates input control signals of the serialized compressed scan circuit 110. In the present embodiment, the input control signals of the serialized compressed scan circuit 110 include a shift enable signal SE, a strobe signal Strobe, a serialized scan clock signal SSC and a scan clock signal SC. Moreover, the test data input signal TDI of the TAP 150 could be coupled to the serialized compressed scan circuit 110 to serve as a serialized scan data input signal SSI, and a serialized scan data output signal SSO of the serialized compressed scan circuit 110 could be serve as the test result data output signal TDO of the TAP 150.

In the present embodiment, the integrated circuit device 190 includes a serialized compressed scan signal generator 120 and a controller 130. The serialized compressed scan signal generator 120 may be implemented with reference to FIG. 3. The controller 130 is coupled to the state enable bus State_Enable_Bus for providing the at least one state enable signal to the control signal generating device 310 of the serialized compressed scan signal generator 120. The controller 130 is coupled to the TAP 150 for receiving the test clock signal TCK, the test mode selection signal TMS and the optional test reset signal TRST from the test equipment. The controller 130 may be a test access port (TAP) controller with a TAP state machine, and the at least one state enable signal on the state enable bus State_Enable_Bus is (are) generated by the TAP state machine of the controller 130 which compliant to IEEE 1149.1 standard. The TAP state machine of the controller 130 may be a finite state machine (FSM) or other state control circuit.

The state transition of the TAP state machine of the controller 130 may be implemented with reference to FIG. 2 and FIG. 7. For example, the TAP state machine of the controller 130 could be the FSM having 16 state values which is compliant to IEEE 1149.1 standard, where a state value stored in a state register represents a state of the FSM. An instruction come from the test equipment (not shown) is loaded to an instruction register of the controller 130. The controller 130 could transit its current state to another one or remain in the same state according to its current state, the test clock signal TCK, the test mode selection signal TMS and the optional test reset signal TRST. The controller 130 generates corresponding state enable signals to indicate the states of the integrated circuit device 190, where the state enable signals generated by the controller 130 construct a state enable bus State_Enable_Bus and are coupled to the serialized compressed scan signal generator 120. The seri-

alized compressed scan signal generator **120** generates a scan clock signal SC, a shift enable signal SE, a strobe signal Strobe and a serialized scan clock signal SSC to the serialized compressed scan circuit **110** according to the test clock signal TCK, the optional test reset signal TRST and the test mode selection signal TMS received from the TAP **150** and the state enable signals of the state enable bus State_Enable_Bus received from the controller **130**. Moreover, the test data input signal TDI of the TAP **150** could be coupled to the serialized compressed scan circuit **110** to serve as a serialized scan data input signal SSI, and a serialized scan data output signal SSO of the serialized compressed scan circuit **110** could be coupled to the multiplexer **140**. Whether the test result data output signal TDO is couple to the serialized scan data output signal SSO or to other test result data to the TAP **150** is determined by the multiplexer **140**.

FIG. **19** illustrates a serialized compressed scan signal generator **120** of FIG. **18** according to an embodiment of the disclosure. The serialized compressed scan signal generator **120** includes a control signal generating device **310**, a clock gating device **320** and a selector **330**. The control signal generating device **310** and the clock gating device **320** of the serialized compressed scan signal generator **120** of FIG. **19** may be implemented with reference to FIG. **3**. The control signal generating device **310** could generate an shift enable signal Shift_en, a strobe signal Strobe and a capture enable signal Capture_en according to the test clock signal TCK, the optional test reset signal TRST and the state enable bus State_Enable_Bus from the controller **130** of FIG. **18**. The clock gating device **320** is a logic circuit and generates a serialized scan clock signal SSC and a scan clock signal SC according to the enable signal Shift_en, the strobe signal Strobe, the capture enable signal Capture_en and the test clock signal TCK. Then, the selector **330** could selectively set the enable signal Shift_en or the strobe signal Strobe as a shift enable signal SE according to a selection signal SEL. Therefore, according to the state enable signal on the state enable bus State_Enable_Bus, the optional test reset signal TRST and the test clock signal TCK, the serialized compressed scan signal generator **120** could generate the serialized scan clock signal SSC, the shift enable signal SE, the strobe signal Strobe and the scan clock signal SC.

FIG. **20** illustrates a serialized compressed scan signal generator **120** of FIG. **19** according to another embodiment of the disclosure. The serialized compressed scan signal generator **120** includes a control signal generating device **310**, a clock gating device **320** and a selector **330**. The control signal generating device **310** comprises OR gates **510** and **520** and negative edge-triggered registers **413-415**. In the present embodiment, the negative edge-triggered registers **413-415** may be flip-flops (FFs). In FIG. **20**, the clock gating device **320** includes an OR gate **421**, an AND gate **422** and an AND gate **423**. The control signal generating device **310** and the clock gating device **320** of the serialized compressed scan signal generator **120** of FIG. **20** may be implemented with reference to FIG. **3**, FIG. **4**, FIG. **5** and FIG. **6**. The first input terminal of the selector **330** is coupled to the control signal generating device **310** for receiving the enable signal Shift_en. The second input terminal of the selector **330** is coupled to the control signal generating device **310** for receiving the strobe signal Strobe. The output terminal of the selector **330** could selectively provide the enable signal Shift_en or the strobe signal Strobe to serve as the shift enable signal SE according to the selection signal SEL. In the present embodiment, the selector **330** is a multiplexer. In other embodiment, the selector **330** may be a switch, a routing circuit or other. In the present embodiment of FIG. **20**, the optional test reset signal TRST could be used to reset the negative edge-triggered registers **413-415**. The signal waveform of the serialized compressed scan signal generator **120** of FIG. **20** may be implemented with reference to FIG. **8**.

FIG. **21** illustrates a serialized compressed scan signal generator **120** of FIG. **19** according to another embodiment of the disclosure. The control signal generating device **310** and the clock gating device **320** of the serialized compressed scan signal generator **120** of FIG. **21** may be implemented with reference to FIG. **3**, FIG. **6**, FIG. **11** and FIG. **12**. The serialized compressed scan signal generator **120** includes a control signal generating device **310**, a clock gating device **320** and a selector **330**. The control signal generating device **310** includes negative edge-triggered registers **611** and **612** and a counter **613**. In the present embodiment, the negative edge-triggered registers **611** and **612** may be flip-flops (FFs), and the counter **613** is a negative edge-triggered counter. In the present embodiment, the optional test reset signal TRST could be used to reset the negative edge-triggered registers **611-612** and the counter **613**. The counter **613** could count a number of negative edges of the test clock signal TCK that the enable signal Shift_en remains enabled, and generates a counting result CNT. When the counting result CNT of the counter **613** is equivalent to the bit length of the deserializer (for example, the deserializer **112** of FIG. **1**) or the serializer (for example, the serializer **113** of FIG. **1**), the counter **613** enables the strobe signal Strobe. For example, it is assumed that the maximum bit length of the deserializer or the serializer is N, when the enable signal Shift_en is enabled, the counter **613** starts to count from an initial value (for example, CNT=0). When the counting result CNT of the counter **613** is N, the counter **613** enables the strobe signal Strobe, and sets the counting result CNT to 1, and continues to count from 1 to N until the enable signal Shift_en is disabled. When the shift enable signal Shift_en is disabled, the counter **613** is reset to the initial value CNT=0 to finish the counting process. In the present embodiment, the counter **613** performs a cyclic counting from 1 to N. In other embodiments, the counter **613** could perform the cyclic counting from a first value to a second value, where a difference of the second value and the first value is the bit length of the serializer or the deserializer minus one (i.e. N−1). The signal waveform of the serialized compressed scan signal generator **120** of FIG. **21** may be implemented with reference to FIG. **13**.

FIG. **22** illustrates a serialized compressed scan signal generator **120** of FIG. **19** according to another embodiment of the disclosure. The control signal generating device **310** and the clock gating device **320** of the serialized compressed scan signal generator **120** of FIG. **22** may be implemented with reference to FIG. **3**, FIG. **6**, FIG. **11** and FIG. **14**. The serialized compressed scan signal generator **120** includes a control signal generating device **310**, the clock gating device **320** and the selector **330**. The control signal generating device **310** includes negative edge-triggered registers **611** and **612** and a counter **613**. Compared to the control signal generating device **310** of FIG. **21**, the control signal generating device **310** of FIG. **22** enables the enable signal Shift_en according to the pause-DR state enable signal Pause-DR on the state enable bus State_Enable_Bus. For example, when the test clock signal TCK is at negative edge, the negative edge-triggered register **611** enables the enable signal Shift_en coupled to the counter **613**, the clock gating device **320** and the selector **330** while the pause-DR state enable signal Pause-DR is enabled. The signal waveform of

the serialized compressed scan signal generator **120** of FIG. **22** may be implemented with reference to FIG. **15**.

FIG. **23** illustrates a serialized compressed scan signal generator **120** of FIG. **19** according to another embodiment of the disclosure. The control signal generating device **310** and the clock gating device **320** of the serialized compressed scan signal generator **120** of FIG. **23** may be implemented with reference to FIG. **3**, FIG. **6**, FIG. **11** and FIG. **16**. The serialized compressed scan signal generator **120** includes a control signal generating device **310**, the clock gating device **320** and the selector **330**. The control signal generating device **310** includes negative edge-triggered registers **611** and **612**, a counter **613** and OR gates **655** and **656**. In the present embodiment, the OR gate **655** generates a signal LS4 according to the shift-DR state enable signal Shift-DR or the pause-DR state enable signal Pause-DR on the state enable bus State_Enable_Bus. When the test clock signal TCK is at negative edge, the negative edge-triggered register **611** generates the enable signal Shift_en to the clock gating device **320** and the selector **330** according to the signal LS4. The OR gate **656** generates a signal LS5 according to the exit1-DR state enable signal Exit1-DR or the exit2-DR state enable signal Exit2-DR on the state enable bus State_Enable_Bus. When the test clock signal TCK is at negative edge, the negative edge-triggered register **612** enables the capture enable signal Capture_en coupled to the clock gating device **320** according to the input signal LS5. The signal waveform of the serialized compressed scan signal generator **120** of FIG. **23** may be implemented with reference to FIG. **17**.

FIG. **24** illustrates a serialized compressed scan signal generator **120** of FIG. **19** according to another embodiment of the disclosure. The control signal generating device **310** and the clock gating device **320** of the serialized compressed scan signal generator **120** of FIG. **24** may be implemented with reference to FIG. **3**, FIG. **4**, FIG. **6** and FIG. **9**. The serialized compressed scan signal generator **120** includes a control signal generating device **310**, the clock gating device **320** and the selector **330**. The control signal generating device **310** includes NOR gates **910** and **930**, an OR gate **940**, flip-flop **920** and negative edge-triggered registers **413-415**. In the present embodiment, the flip-flop **920** is a positive edge-triggered register. The optional test reset signal TRST could be used to reset the flip-flop **920** and negative edge-triggered registers **413-415**. When the test clock signal TCK is at positive edge, the flip-flop **920** latches and output the output signal of the NOR gates **910** to serve as the signal LS3. When the test clock signal TCK is at negative edge, the negative edge-triggered register **415** latches and output the signal LS3 to serve as the capture enable signal Capture_en. Moreover, a first input terminal of the NOR gate **930** couples to an inversion logic value of the pause-DR state enable signal Pause-DR on the state enable bus State_Enable_Bus, a second input terminal of the NOR gate **930** couples to the signal LS3, and an output terminal of the NOR gate **930** couples to a data input terminal of the negative edge-triggered register **414** and a first input terminal of the OR gate **940**. When the test clock signal TCK is at negative edge, the negative edge-triggered register **414** latches and output the signal LS2 to serve as the strobe signal Strobe. A second input terminal of the OR gate **940** couples to the shift-DR state enable signal Shift-DR on the state enable bus State_Enable_Bus, a third input terminal of the OR gate **940** couples to the exit1-DR state enable signal Exit1-DR on the state enable bus State_Enable_Bus, a fourth input terminal of the OR gate **940** couples to the exit2-DR state enable signal Exit2-DR on the state enable bus State_Enable_Bus, and an output terminal of the OR gate **940** output the signal LS1 to a data input terminal of the negative edge-triggered register **413**. When the test clock signal TCK is at negative edge, the negative edge-triggered register **413** latches and outputs the signal LS **1** to serve as the enable signal Shift_en. The signal waveform of the serialized compressed scan signal generator **120** of FIG. **24** may be implemented with reference to FIG. **10**.

The serialized compressed scan signal generator of the disclosure is suitable for integrating a test circuit of an integrated circuit, and is capable of converting a signal of the TAP into a signal required by the serialized compressed scan test, i.e. the serialized compressed scan test is performed through an IEEE1149.1 compliant TAP controller. When the serialized compressed scan test is performed, the serialized compressed scan signal generator of the disclosure generates a test control signal required by a serialized compressed scan test circuit, so as to generate continuous and uninterrupted serialized scan clock signals and scan clock signals to control the serialized compressed scan test circuit. Therefore, a process of transmitting the test data input to the scan chains through the deserializer and a process of transmitting the test result captured from the scan chains to the serializer are all uninterrupted. Therefore, a test interface conversion circuit design of non-loss or high conversion rate and an operation method thereof are provided.

According to the embodiments of the disclosure, by executing the test interface signal conversion, the serialized compressed scan signal generator **120** could be controlled through the TAP of the boundary scan test to generate the signal required by the serialized compressed scan signal test, so as to perform the serialized compressed test through a boundary scan circuit. Therefore, the test time, the test data volume and the number of test pins of the chip could be reduced which results to the test cost decreased, and the process of test integration for an IC is also improved.

It will be apparent to those skilled in the art that various modifications and variations could be made to the structure of the disclosed embodiments without departing from the scope or spirit of the disclosure. In view of the foregoing, it is intended that the disclosure cover modifications and variations of this disclosure provided they fall within the scope of the following claims and their equivalents.

What is claimed is:

1. An integrated circuit device, configured to generate input control signals of a serialized compressed scan circuit, comprising:

- a clock input port, configured to receive a test clock signal;
- a state enable bus, configured to receive at least one state enable signal;
- a control signal generating device, coupled to the state enable bus for receiving the state enable signal, coupled to the clock input port for receiving the test clock signal, and correspondingly generating a shift enable signal, a capture enable signal and a strobe signal; and
- a clock gating device, coupled to the control signal generating device for receiving the shift enable signal, the capture enable signal and the strobe signal, and coupled to the clock input port for receiving the test clock signal, wherein the clock gating device, in responding to the test clock signal, generates a serialized scan clock signal when the shift enable signal is enabled and generates a scan clock signal when the strobe signal or the capture enable signal is enabled, wherein the serialized scan clock signal and the scan clock signal are part of the input control signals.

2. The integrated circuit device as claimed in claim 1, wherein the control signal generating device comprises:

a logic operation circuit, coupled to the state enable bus for receiving an exit1-data-register state enable signal, an exit2-data-register state enable signal, a shift-data-register state enable signal, a pause-data-register state enable signal and a capture-data-register state enable signal, and correspondingly generating a first logic signal, a second logic signal and a third logic signal;

a first negative edge-triggered register, having an input terminal coupled to the logic operation circuit for receiving the first logic signal, a negative edge-triggered terminal coupled to the clock input port for receiving the test clock signal, and an output terminal coupled to the clock gating device for providing the shift enable signal;

a second negative edge-triggered register, having an input terminal coupled to the logic operation circuit for receiving the second logic signal, a negative edge-triggered terminal coupled to the clock input port for receiving the test clock signal, and an output terminal coupled to the clock gating device for providing the strobe signal; and

a third negative edge-triggered register, having an input terminal coupled to the logic operation circuit for receiving the third logic signal, a negative edge-triggered terminal coupled to the clock input port for receiving the test clock signal, and an output terminal coupled to the clock gating device for providing the capture enable signal.

3. The integrated circuit device as claimed in claim 2, wherein the first logic signal is enabled when the exit1-data-register state enable signal, the exit2-data-register state enable signal, the shift-data-register state enable signal or the pause-data-register state enable signal is enabled,

wherein the second logic signal is enabled when the exit1-data-register state enable signal or the exit2-data-register state enable signal is enabled, and

wherein the third logic signal is enabled when the capture-data-register state enable signal is enabled.

4. The integrated circuit device as claimed in claim 3, wherein the logic operation circuit comprises:

a first OR gate having a first input terminal coupled to the state enable bus for receiving the shift-data-register state enable signal, a second input terminal coupled to the state enable bus for receiving the pause-data-register state enable signal, and an output terminal generating the first logic signal to the input terminal of the first negative edge-triggered register;

a second OR gate having a first input terminal coupled to the state enable bus for receiving the exit1-data-register state enable signal, a second input terminal coupled to the state enable bus for receiving the exit2-data-register state enable signal, and an output terminal coupled to a third input terminal of the first OR gate and generating the second logic signal to the input terminal of the second negative edge-triggered register; and

a wire having a first terminal coupled to the state enable bus for receiving the capture-data-register state enable signal, and a second terminal outputting the capture-data-register state enable signal to serve as the third logic signal.

5. The integrated circuit device as claimed in claim 2, wherein the logic operation circuit comprises:

a first NOR gate having an inverting input terminal coupled to the state enable bus for receiving the pause-data-register state enable signal, and a non-inverting input terminal configured to receive a test mode selection signal;

a flip-flop having an input terminal coupled to an output terminal of the first NOR gate, a positive edge-triggered terminal coupled to the clock input port for receiving the test clock signal, and an output terminal providing the third logic signal to the third negative edge-triggered register;

a second NOR gate having an inverting input terminal coupled to the state enable bus for receiving the pause-data-register state enable signal, a non-inverting input terminal coupled to the output terminal of the flip-flop, and an output terminal providing the second logic signal to the second negative edge-triggered register; and

an OR gate having a first input terminal coupled to the output terminal of the second NOR gate, a second input terminal coupled to the state enable bus for receiving the shift-data-register state enable signal, a third input terminal coupled to the state enable bus for receiving the exit1-data-register state enable signal, a fourth input terminal coupled to the state enable bus for receiving the exit2-data-register state enable signal, and an output terminal providing the first logic signal to the first negative edge-triggered register.

6. The integrated circuit device as claimed in claim 2, wherein the first negative edge-triggered register, the second negative edge-triggered register and the third negative edge-triggered register are reset by an optional test reset signal.

7. The integrated circuit device as claimed in claim 1, wherein the control signal generating device comprises:

a logic operation circuit, coupled to the state enable bus for receiving the at least one state enable signal, and correspondingly generating a first logic signal and a second logic signal;

a first negative edge-triggered register, having an input terminal coupled to the logic operation circuit for receiving the first logic signal, a negative edge-triggered terminal coupled to the clock input port for receiving the test clock signal, and an output terminal coupled to the clock gating device for providing the shift enable signal;

a second negative edge-triggered register, having an input terminal coupled to the logic operation circuit for receiving the second logic signal, a negative edge-triggered terminal coupled to the clock input port for receiving the test clock signal, and an output terminal coupled to the clock gating device for providing the capture enable signal; and

a negative edge-triggered counter, having an input terminal coupled to the output terminal of the first negative edge-triggered register for receiving the shift enable signal, a negative edge-triggered terminal coupled to the clock input port for receiving the test clock signal, and an output terminal coupled to the clock gating device for providing the strobe signal, wherein cyclic counting of the negative edge-triggered counter from a first value to a second value is activated when the shift enable signal is enabled and the test clock signal is at negative edge.

8. The integrated circuit device as claimed in claim 7, wherein the negative edge-triggered counter is reset to an initial value when the shift enable signal is disabled, and a difference between the second value and the first value is a serializer bit length minus one or a deserializer bit length minus one.

9. The integrated circuit device as claimed in claim 7, wherein the logic operation circuit comprises:

a first OR gate having a first input terminal coupled to the state enable bus for receiving a shift-data-register state enable signal, a second input terminal coupled to the state enable bus for receiving a pause-data-register state enable signal, and an output terminal generating the first logic signal to the input terminal of the first negative edge-triggered register; and

a second OR gate having a first input terminal coupled to the state enable bus for receiving an exit1-data-register state enable signal, a second input terminal coupled to the state enable bus for receiving an exit2-data-register state enable signal, and an output terminal generating the second logic signal to the input terminal of the second negative edge-triggered register.

10. The integrated circuit device as claimed in claim 7, wherein the logic operation circuit comprises:

a first wire having a first terminal coupled to the state enable bus for receiving a shift-data-register state enable signal, and a second terminal outputting the shift-data-register state enable signal to serve as the first logic signal; and

a second wire having a first terminal coupled to the state enable bus for receiving a capture-data-register state enable signal, and a second terminal outputting the capture-data-register state enable signal to serve as the second logic signal.

11. The integrated circuit device as claimed in claim 7, wherein the logic operation circuit comprises:

a first wire having a first terminal coupled to the state enable bus for receiving a pause-data-register state enable signal, and a second terminal outputting the pause-data-register state enable signal to serve as the first logic signal; and

a second wire having a first terminal coupled to the state enable bus for receiving a capture-data-register state enable signal, and a second terminal outputting the capture-data-register state enable signal to serve as the second logic signal.

12. The integrated circuit device as claimed in claim 7, wherein the first negative edge-triggered register, the second negative edge-triggered register and the negative edge-triggered counter are reset by an optional test reset signal.

13. The integrated circuit device as claimed in claim 1, wherein the clock gating device comprises:

an OR gate having a first input terminal coupled to the control signal generating device for receiving the strobe signal, and a second input terminal coupled to the control signal generating device for receiving the capture enable signal;

a first AND gate having a first input terminal coupled to an output terminal of the OR gate, a second input terminal coupled to the clock input port for receiving the test clock signal, and an output terminal generating the scan clock signal to the serialized compressed scan circuit; and

a second AND gate having a first input terminal coupled to the control signal generating device for receiving the shift enable signal, a second input terminal coupled to the clock input port for receiving the test clock signal, and an output terminal generating the serialized scan clock signal to the serialized compressed scan circuit.

14. The integrated circuit device as claimed in claim 1, further comprising:

a selector having a first input terminal coupled to the control signal generating device for receiving the shift enable signal, a second input terminal coupled to the control signal generating device for receiving the strobe signal, and an output terminal outputting the shift enable signal or the strobe signal to the serialized compressed scan circuit.

15. The integrated circuit device as claimed in claim 14, wherein the selector comprises a multiplexer.

16. The integrated circuit device as claimed in claim 1, further comprising:

a controller, coupled to the state enable bus for providing the at least one state enable signal.

17. The integrated circuit device as claimed in claim 16, wherein the controller is a test access port (TAP) controller with a TAP state machine, and the at least one state enable signal is (are) generated by the TAP state machine which compliant to IEEE 1149.1 standard.

18. A method for generating input control signals of a serialized compressed scan circuit, comprising:

generating a shift enable signal, a capture enable signal and a strobe signal according to at least one state enable signal transmitted from a state enable bus and a test clock signal transmitted from a clock input port;

generating a serialized scan clock signal when the shift enable signal is enabled and generating a scan clock signal when the strobe signal or the capture enable signal is enabled in responding to the test clock signal transmitted from the clock input port,

wherein the serialized scan clock signal and the scan clock signal are part of the input control signals.

19. The method as claimed in claim 18, wherein the step of generating a shift enable signal, a capture enable signal and a strobe signal comprises:

generating a first logic signal, a second logic signal and a third logic signal according to an exit1-data-register state enable signal, an exit2-data-register state enable signal, a shift-data-register state enable signal, a pause-data-register state enable signal and a capture-data-register state enable signal transmitted from the state enable bus;

latching the first logic signal according to the test clock signal, so as to provide the shift enable signal;

latching the second logic signal according to the test clock signal, so as to provide the strobe signal; and

latching the third logic signal according to the test clock signal, so as to provide the capture enable signal.

20. The method as claimed in claim 19, wherein the step of generating a first logic signal, a second logic signal and a third logic signal comprises:

enabling the first logic signal when the exit1-data-register state enable signal, the exit2-data-register state enable signal, the shift-data-register state enable signal or the pause-data-register state enable signal is enabled;

enabling the second logic signal when the exit1-data-register state enable signal or the exit2-data-register state enable signal is enabled; and

enabling the third logic signal when the capture-data-register state enable signal is enabled.

21. The method as claimed in claim 19, wherein the step of generating a first logic signal, a second logic signal and a third logic signal comprises:

configuring a first NOR gate having an inverting input terminal and a non-inverting input terminal, wherein the inverting input terminal of the first NOR gate is coupled to the state enable bus for receiving the pause-data-register state enable signal, and the non-inverting input terminal of the first NOR gate is configured to receive a test mode selection signal;

configuring a flip-flop having an input terminal, a positive edge-triggered terminal and an output terminal, wherein the input terminal of the flip-flop is coupled to an output terminal of the first NOR gate, the positive edge-triggered terminal of the flip-flop is coupled to the clock input port for receiving the test clock signal, and the output terminal of the flip-flop provides the third logic signal;

configuring a second NOR gate having an inverting input terminal, a non-inverting input terminal and an output terminal, wherein the inverting input terminal of the second NOR gate is coupled to the state enable bus for receiving the pause-data-register state enable signal, the non-inverting input terminal of the second NOR gate is coupled to the output terminal of the flip-flop, and the output terminal of the second NOR gate provides the second logic signal; and

configuring an OR gate having a first input terminal, a second input terminal, a third input terminal, a fourth input terminal and an output terminal, wherein the first input terminal of the OR gate is coupled to the output terminal of the second NOR gate, the second input terminal of the OR gate is coupled to the state enable bus for receiving the shift-data-register state enable signal, the third input terminal of the OR gate is coupled to the state enable bus for receiving the exit1-data-register state enable signal, the fourth input terminal of the OR gate is coupled to the state enable bus for receiving the exit2-data-register state enable signal, and the output terminal of the OR gate provides the first logic signal.

22. The method as claimed in claim **18**, wherein the step of generating a shift enable signal, a capture enable signal and a strobe signal comprises:

generating a first logic signal and a second logic signal according to the at least one state enable signal transmitted from the state enable bus;

latching the first logic signal according to the test clock signal, so as to provide the shift enable signal;

latching the second logic signal according to the test clock signal, so as to provide the capture enable signal; and

cyclic counting the test clock signal from a first value to a second value according to the shift enable signal, so as to provide the strobe signal.

23. The method as claimed in claim **22**, wherein a difference between the second value and the first value is a serializer bit length minus one or a deserializer bit length minus one.

24. The method as claimed in claim **22**, wherein the step of generating first logic signal and a second logic signal comprises:

enabling the first logic signal when a shift-data-register state enable signal transmitted from the state enable bus or a pause-data-register state enable signal transmitted from the state enable bus is enabled; and

enabling the second logic signal when an exit1-data-register state enable signal transmitted from the state enable bus or an exit2-data-register state enable signal transmitted from the state enable bus is enabled.

25. The method as claimed in claim **22**, wherein the step of generating first logic signal and a second logic signal comprises:

enabling the first logic signal when a shift-data-register state enable signal transmitted from the state enable bus is enabled; and

enabling the second logic signal when a capture-data-register state enable signal transmitted from the state enable bus is enabled.

26. The method as claimed in claim **22**, wherein the step of generating first logic signal and a second logic signal comprises:

enabling the first logic signal when a pause-data-register state enable signal transmitted from the state enable bus is enabled; and

enabling the second logic signal when a capture-data-register state enable signal transmitted from the state enable bus is enabled.

27. The method as claimed in claim **18**, wherein the step of controlling the test clock signal as the scan clock signal comprises:

configuring an OR gate having a first input terminal and a second input terminal, wherein the first input terminal of the OR gate receives the strobe signal, and the second input terminal of the OR gate receives the capture enable signal; and

configuring a AND gate having a first input terminal, a second input terminal and an output terminal, wherein the first input terminal of the AND gate is coupled to an output terminal of the OR gate, the second input terminal of the AND gate receives the test clock signal, and the output terminal of the AND gate generates the scan clock signal to the serialized compressed scan circuit.

28. The method as claimed in claim **18**, wherein the step of controlling the test clock signal as the serialized scan clock signal comprises:

configuring a AND gate having a first input terminal, a second input terminal and an output terminal, wherein the first input terminal of the AND gate receives the shift enable signal, the second input terminal of the AND gate receives the test clock signal, and the output terminal of the AND gate generates the serialized scan clock signal to the serialized compressed scan circuit.

29. The method as claimed in claim **18**, further comprising:

selecting the shift enable signal or the strobe signal to the serialized compressed scan circuit.

30. The method as claimed in claim **18**, wherein the at least one state enable signal is (are) generated by a test access port (TAP) controller with a TAP state machine which compliant to IEEE 1149.1 standard.
