(57) **ABSTRACT**

Providing an electrode structure capable of realizing an electrode array which allows each of the electrodes to be individually controlled while allowing them to be densely arranged and placed in a living body. According to the present invention, an electrode control circuit electrically connected to an electrode body is fixed to a rear portion of the electrode body within a front-viewed contour of the electrode body. This electrode control circuit may be contained in a recess formed in the rear portion of the electrode body, or it may be fixed to the back face of the electrode body. Conversely, an electrically conductive material layer covering the electrode control circuit may be used as the electrode body. A plurality of such bioelectrodes may be arranged in a two-dimensional form on a substrate or connected by a connection line including an electrical wire. Such configurations allow the bioelectrodes to be densely arranged.

## HIGH-FUNCTIONALITY BIOELECTRODE

## TECHNICAL FIELD

The present invention relates to a bioelectrode to be attached to a living body (such as an organ of various experimental animals or that of a man) so as to give electrical stimuli to that living body or measure an electric potential, electric current or similar quantity in that living body.

## BACKGROUND ART

Electrode arrays having a number of electrodes arranged in various patterns are used as a nerve interface for electrically stimulating a nerve or measuring a nerve action potential. To fulfill this intended purpose, the electrode array should be implanted in a living body and the wires which are bonded to the metallic (e.g. platinum) electrodes should be connected to a stimulator or measurement apparatus. As one method for enabling the multielectrode configuration of the electrode array, the technique of equipping each individual electrode with a small semiconductor chip capable of performing electrode control as well as other functions has been proposed and demonstrated (high-function electrode).

For example, in the case where the sense of sight has been lost due to dysfunction of the visual cells in the retina for converting light into electric signals (examples of the dysfunction include age-related macular degeneration and retinitis pigmentosa), while there is no problem in the ganglion cells in the retina or the optic nerves connecting the retina and the brain, the vision can be virtually restored by taking a visual image of the scene in front of the eyes using a camera or similar device and giving the ganglion cells or other remaining retinal cells two-dimensional electrical stimuli corresponding to that image. Such a system for providing a vision substitution by giving electrical stimuli to the retina is called the "artificial vision device" (for example, see Patent Literature 1).

Non Patent Literature 1 discloses a visual stimulation experiment performed on a rabbit using an artificial vision device employing suprachoroidal transretinal stimulation (STS). The measurement was performed as follows: As shown in FIGS. 1A and 1B, a flexible substrate with an array of 3x3 electrodes arranged as shown in FIG. 3 was planted in an eyeball (sclera) of a rabbit, and electrical stimuli were given to the retina from the choroid side. Meanwhile, electrodes were attached to the visual cortex on the brain of the rabbit, and the electric potential at that point (electrically evoked visual potentials) was measured.

The amount of electric current supplied to the electrodes attached to the eyeball was set at various values and the change in the brain wave was measured, with the point in time of the supply of the electric current (or stimulus) defined as the zero point. Consequently, as shown in FIG. 2, it was confirmed that the peak height (response) of the brain wave increases with an increase in the current value (stimulus). The time delay from the stimulation (approximately 20 msec) was roughly equal to the transmission delay of the vision investigated by another experiment. These facts confirm that this electrode array substrate **80** (in FIG. 3) was correctly acting as an eyeball-stimulating electrode.

## SUMMARY OF INVENTION

## Technical Problem

As shown in FIG. 3, the electrode array substrate **80** described in Non Patent Literature 1 has an electrode control circuit chip **82** for each electrode **81** to control the amount and timing of the electric current or voltage supplied to the electrode **81** as well as other parameters. This configuration requires only four wires (for positive and negative power sources as well as first and second operation control lines) to be connected to the entire substrate regardless of the number of electrodes **81**, thus allowing a considerable number of electrodes **81** to be embedded in a living body (e.g. an eyeball).

The electrode control circuit chip **82** for controlling each electrode **81** is small in size. However, the spacing of the electrodes **81** cannot be small since the chip space must be provided for each individual electrode **81** as shown in FIG. 4. Therefore, in particular, it is difficult to densely arrange the electrodes **81** in a small part (e.g. eyeball) of the living body.

The present invention has been developed in view of the previously described problem. Its primary objective is to provide an electrode structure capable of realizing an electrode array which allows each of the electrodes to be individually controlled while allowing them to be densely arranged and placed in a living body.

## Solution to Problem

A bioelectrode according to the present invention developed for achieving the aforementioned objective is characterized in that an electrode control circuit electrically connected to an electrode body is fixed to a rear portion of the electrode body within a front-viewed contour of the electrode body.

The phrase "within a front-viewed contour of the electrode body" means that the portion concerned lies within the contour of the electrode body when the electrode body is viewed from the side that is to be in contact with, pushed onto or stuck into a living body (the front side of the electrode body).

Specifically, the electrode control circuit may be contained in a recess formed in the rear portion of the electrode body. It is also possible to fix the circuit to the back face (rear face) of the electrode body, without forming any recess in the rear portion of the electrode body. Furthermore, as opposed to forming a recess in a solid electrode body and containing the circuit in that recess, the electrode control circuit may be covered with an electrically conductive layer and use this layer as the electrode body.

These bioelectrodes may be singly used. Alternatively, they can be arranged in a two-dimensional form (array) on a substrate and used as an electrode array, or be connected

by a connection line including an electrical wire and used as a connection-type bioelectrode.

#### Advantageous Effects of the Invention

In the bioelectrode according to the present invention, since the control circuit for controlling the electrode body is fixed to the rear portion of the electrode body within the front-viewed contour of the electrode body, the electrode body can be implanted in a compact area of a living body without additionally providing a lateral space for the electrode control circuit. This is particularly advantageous when many electrode bodies need to be implanted in a living body, since the electrode bodies can be densely arranged so as to give stimuli to the living body or measure biopotential or other quantities at a higher level of planar (or linear) density.

By forming a recess in the rear portion of the electrode body and containing the electrode control circuit in that recess, the entire length of the bioelectrode inclusive of the electrode body and the electrode control circuit can be reduced. In the case of implanting this bioelectrode in a living body, a liquid-tight separation between the electrode control circuit and the living body can be achieved by simply sealing the open side of the recess. Therefore, it is easy to prevent both the invasion on the living body by the electrode control circuit and the invasion of biological solutions into the electrode control circuit.

#### BRIEF DESCRIPTION OF DRAWINGS

FIGS. 1A and 1B are illustrations showing the setup of a visual stimulation experiment performed on a rabbit using an artificial vision device.

FIG. 2 is a graph showing the magnitude of the stimulus and the change in the brain wave, which is a result of the aforementioned visual stimulation experiment performed on the rabbit.

FIG. 3 is a plan view of the electrode array substrate used in the aforementioned visual stimulation experiment performed on the rabbit.

FIG. 4 is a sectional view showing the structure of the electrode array substrate used in the aforementioned visual stimulation experiment performed on the rabbit.

FIGS. 5A-5C are a side view, sectional view and bottom view, respectively, of a bullet-shaped electrode body used in an artificial vision device as one embodiment of the bioelectrode according to the present invention.

FIG. 6 is a plan view of an electrode control circuit chip used in the artificial vision device of the aforementioned embodiment.

FIG. 7 is a sectional view showing the structure of an electrode array substrate used in the artificial vision device of the aforementioned embodiment.

FIG. 8 is a perspective view of the electrode array substrate used in the artificial vision device of the aforementioned embodiment.

FIG. 9 is a sectional view showing the structure of an electrode array substrate using an electrode body as another embodiment of the present invention.

FIG. 10 is a sectional view showing the structure of an electrode array substrate using a plate-shaped electrode body as another embodiment of the present invention.

FIG. 11 is a sectional view showing the structure of an electrode array substrate using a coating electrode body as another embodiment of the present invention.

FIGS. 12A-12C are sectional views of other embodiments of the present inventions, where FIG. 12A is a bioelectrode

with the control circuit fixed to the rear face, FIG. 12B is a bioelectrode with the control circuit encapsulated, and FIG. 12C is a bioelectrode coated with an electrically conductive resin or ceramic encapsulation material.

FIG. 13 is a perspective view of a connection-type bioelectrode consisting of the bioelectrodes connected by a connection line including a conductor wire.

FIGS. 14A and 14B are model views showing application examples of the connection-type bioelectrode, where FIG. 14A shows an application to an eyeball and FIG. 14B shows an application to a brain.

#### DESCRIPTION OF EMBODIMENTS

An artificial vision device as one embodiment of the bioelectrode according to the present invention is hereinafter described. As shown in FIGS. 5A-5C, the bioelectrode 10 used in the artificial vision device of the present embodiment uses a bullet-shaped electrode body 11. The electrode body 11 may be made of any material compatible with living bodies. Examples of the available materials include: metallic materials, such as platinum (Pt), gold (Au), titanium (Ti) or an alloy of these kinds of metal; electrically conductive compounds, such as iridium oxide (IrOx) or titanium nitride (TiN); and electrically conductive polymers, such as poly (3,4-ethylenedioxythiophene) or PEDOT. Naturally, it is also possible to use such electrically conductive materials for the surface coating while creating the inner part of the electrode body from resin, ceramic or other non-conductive materials. In the case of using an inner part made of a resin, ceramic or similar non-conductive material, it is necessary to form an electrical channel between the electrode control circuit chip and the electrically conductive coating on the surface (as will be described later). Compared to resin, using a metallic or ceramic material allows the electrode control circuit chip to be encapsulated for a longer period of time within a hermetic space surrounded by the metallic or ceramic material. Accordingly, it is preferable to use a metallic material for the electrode body 11 or create the inner part of the electrode body 11 from ceramic. In this case, the electrode body 11 can double as the encapsulation material (which will be described later). Although the following descriptions deal with the case of a bullet-shaped electrode body 11 with a size of 500  $\mu\text{m}$ , the present invention is not limited to this size but may have any size that allows the electrode body to be implanted in a living body, e.g. from 10  $\mu\text{m}$  to 500  $\mu\text{m}$ . The "size" of the electrode body 11 in the present context means the depth, width or height of the electrode body 11, whichever is the largest.

As shown in FIGS. 5B and 5C, the electrode body 11 of the present embodiment has, in its rear portion, a recess 12 for containing an electrode control circuit chip 20.

The electrode control circuit chip 20 is a single chip on which a circuit for controlling electric current and/or voltage supplied to the electrode body 11 is created. As shown in FIG. 6, it includes five electrode pads 21a-21e and three control circuits (or similar elements) 22a-22c arranged among those pads. The electrode pads 21c and 21d are the terminals for receiving positive and negative DC power from an external source, while the electrode pads 21a and 21b are the terminals for receiving externally-supplied operation control signals. As will be described later, these four electrode pads 21a-21d are individually and respectively connected to the four electrical wires provided in a substrate 31. Based on the operation control signals thus supplied from an external control circuit, the electrode control circuit chip 20 performs various mathematical opera-

5

tions and appropriately controls the electric current and/or voltage supplied from the positive and negative power sources so that a controlled amount of current and/or voltage will be fed to the central electrode pad **21e**. The electric current and/or voltage fed to the electrode pad **21e** is supplied to the electrode body **11** through a wire provided in the substrate **31**.

This electrode control circuit chip **20** is contained in the recess **12** in the rear portion of the electrode body **11** and fixed by filling the surrounding space with a resin or similar material. In other words, the electrode control circuit chip **20** is encapsulated in the recess **12** in the rear portion of the electrode body **11** with a resin or similar encapsulation material. A resin, metallic or ceramic material can be used as the encapsulation material. Compared to resin, using a metallic or ceramic material allows the electrode control circuit chip to be encapsulated for a longer period of time within an hermetic space surrounded by the metallic or ceramic material. Therefore, they can be suitably used as the encapsulation material for implantation in a living body. When the electrode control circuit chip **20** is inserted into the electrode body **11**, these two components should be oriented in a specified way, and furthermore, a mark should be put on the outside of the electrode body **11** so that one can locate the position of the contained electrode control circuit chip **20** around the axis.

As shown in FIG. 8, a plurality of electrode bodies **11** (bioelectrodes **10**) each of which has the electrode control circuit chip **20** contained in the recess **12** in its rear portion are two-dimensionally arranged on and fixed to a flexible substrate **31**. In this process, each electrode body **11** should be placed at a specific position and in a specific direction with respect to the substrate **31** so that the electrode pads **21a-21e** of the electrode control circuit chip **20** will be correctly brought into electrical connection with the counterpart electrode pads on the substrate **31**. As a result, as shown in FIG. 7, the wires **32** provided in the substrate **31** are connected to the electrode pads **21a-21e** of the electrode control circuit chip **20**, allowing the operation control signals and power from external sources to be correctly supplied to each electrode control circuit chip **20**. The region surrounding the bottom portion of the electrode body **11** placed on the substrate **31** is sealed with a sealant **33**.

As shown in FIG. 8, the electrode array substrate **30** thus created as one example of the bioelectrode substrate has the bioelectrodes **10** densely arranged without the electrode control circuit chips **20** placed in between. Therefore, it is possible to give precise electrical stimuli to target sites of the living body. Since the electrode control circuit chip **20** is contained in the recess **12** of each electrode body **11** and sealed on the flexible substrate **31** with the sealant **33**, the various component substances in the electrode control circuit chip **20** will not penetrate into the living body. Thus, the living body is safely protected and can be correctly tested without being influenced by those substances. Conversely, biological solutions are prevented from invading into the electrode control circuit chip **20** and corroding the electric circuits or obstructing electrical conduction. Such characteristics of the bioelectrode **10** are important since, in some cases, the implanted bioelectrode **10** needs to be left in the living body for a number of years.

Another example of the bioelectrode according to the present invention is shown in FIG. 9. This bioelectrode **50** is similar to the previous embodiment in that the electrode control circuit chip **20** is contained in the recess in the rear portion of the electrode body **11**. The characteristic point is that the supply of the electric current and/or voltage from the

6

electrode control circuit chip **20** to the electrode body **11** is directly performed from an electrode pad **51** provided in the upper portion (on the side closer to the tip of the electrode body **11**) of the electrode control circuit chip **20** to the electrode body **11**. This configuration simplifies the pattern of the conductor wires in the substrate **31**.

In any of the previously described examples, the electrode body **11** is bullet shaped. However, as shown in FIG. 10, the electrode body **15** may be shaped like a plate having a circular or rectangular form (or any other form).

Furthermore, as opposed to those examples in which a solid body of an electrically conductive material is used as the electrode body and the electrode control circuit chip is contained in the recess formed in that body, a bioelectrode **60** as shown in FIG. 11 may be constructed by covering the electrode control circuit chip **20** with an electrically conductive material layer **16** formed by application, plating or similar processes.

Furthermore, as shown in FIG. 12A, it is possible to fix the electrode control circuit chip **20** to the rear portion of the electrode body **70a** instead of containing it in the electrode body. In this case, the electrode control circuit chip **20** is fixed to the electrode body **70a** by attaching it to the electrode body **70a** with its electrode pads electrically in contact with the rear portion of the electrode body **70a**, and subsequently covering it with a resin material **70b** or the like and curing the material. In other words, the electrode control circuit chip **20** is encapsulated on the rear portion of the electrode body **70a** with the resin material **70b** as the encapsulation material. This bioelectrode **70** is not fixed to the substrate **31** as in the previous embodiments, and therefore, can be singly used. For example, as shown in FIG. 13, it is possible to create, as one example of the bioelectrode connection line, a connection-type bioelectrode **90** having a plurality of bioelectrodes **70** connected by a connection line **75**. Connecting the bioelectrodes **70** by the connection line **75** including a conductor wire allows the bioelectrodes **70** to be arbitrarily arranged at desired sites of a living body. FIG. 14A shows an example of attaching the electrodes to the fundus of the eyeball, while FIG. 14B shows an example of attaching them to the brain. For such an application using the connection line, a bioelectrode **71** as shown in FIG. 12B can also be used, in which the electrode control circuit **20** is encapsulated in the bioelectrode **71** using an electrically conductive material **71a** as the encapsulation material (including the case where this is a metallic material). A similar bioelectrode **72** is shown in FIG. 12C, which can be obtained by encapsulating the electrode control circuit **20** with an electrically non-conductive resin, ceramic or similar material **72a** as the encapsulation material forming the inner part of the bioelectrode **72**, and subsequently coating this part with an electrically conductive material **72b**.

The invention claimed is:

1. A bioelectrode substrate, comprising:  
a substrate; and  
a plurality of bioelectrodes fixed to the substrate, wherein:  
each of the plurality of bioelectrodes has a bullet-shaped  
or plate-shaped electrode body and an electrode control  
circuit chip electrically connected to the electrode body  
for controlling electric current and voltage supplied to  
the electrode body upon receiving an externally-sup-  
plied operation signal, and the electrode control circuit  
chip is fixed to a rear portion of the electrode body  
within a front-viewed contour of the electrode body.
2. The bioelectrode substrate according to claim 1,  
wherein the bioelectrode substrate is an optic nerve-stimu-  
lating electrode substrate for stimulating an optic nerve  
through a retina.
3. The bioelectrode substrate according to claim 1,  
wherein the electrode control circuit chip is contained in a  
recess formed in the rear portion of the electrode body.
4. The bioelectrode substrate according to claim 1,  
wherein the electrode control circuit chip is hermetically or  
liquid-tightly sealed in the rear portion of the electrode body  
with an encapsulation material.
5. The bioelectrode substrate according to claim 4,  
wherein the encapsulation material is a resin, metallic or  
ceramic material.
6. The bioelectrode substrate according to claim 1,  
wherein the electrode body is made of a metallic material  
which is platinum, titanium, gold or an alloy of these kinds  
of metal, or is made of an electrically conductive material  
which is an electrically conductive compound or an electri-  
cally conductive polymer.
7. The bioelectrode substrate according to claim 1,  
wherein each of the plurality of bioelectrodes has a size

within a range from 10 μm to 500 μm, where the size is  
defined as a depth, width or height of the bioelectrode,  
whichever is a largest.

8. A bioelectrode connection line, comprising:  
a connection line including an electrical wire; and  
a plurality of bioelectrodes connected by the connection  
line, wherein:  
each of the plurality of bioelectrodes has a bullet-shaped  
or plate-shaped electrode body and an electrode control  
circuit chip electrically connected to the electrode body  
for controlling electric current and voltage supplied to  
the electrode body upon receiving an externally-sup-  
plied operation signal, and the electrode control circuit  
chip is fixed to a rear portion of the electrode body  
within a front-viewed contour of the electrode body.
9. The bioelectrode connection line according to claim 8,  
wherein the bioelectrode connection line is an optic nerve-  
stimulating electrode connection line for stimulating an  
optic nerve through a retina.
10. The bioelectrode connection line according to claim 8,  
wherein the bioelectrode connection line is a brain-stimu-  
lating electrode connection line for stimulating a brain.
11. The bioelectrode connection line according to claim 8,  
wherein the electrode control circuit chip is contained in a  
recess formed in the rear portion of the electrode body.
12. The bioelectrode connection line according to claim 8,  
wherein the electrode control circuit chip is hermetically or  
liquid-tightly sealed in the rear portion of the electrode body  
with an encapsulation material.
13. The bioelectrode connection line according to claim  
12, wherein the encapsulation material is a resin, metallic or  
ceramic material.
14. The bioelectrode connection line according to claim 8,  
wherein the electrode body is made of a metallic material  
which is platinum, titanium, gold or an alloy of these kinds  
of metal, or is made of an electrically conductive material  
which is an electrically conductive compound or an electri-  
cally conductive polymer.
15. The bioelectrode connection line according to claim 8,  
wherein each of the plurality of bioelectrodes has a size  
within a range from 10 μm to 500 μm, where the size is  
defined as a depth, width or height of the bioelectrode,  
whichever is a largest.
